# THE IAU-SOFA SOFTWARE LIBRARIES

SOFA stands for "Standards Of Fundamental Astronomy". The SOFA software libraries are a collection of subprograms, in source-code form, which implement official IAU algorithms for fundamental-astronomy computations. The subprograms at present comprise 131 "astronomy" routines supported by 55 "vector/matrix" routines, available in both Fortran77 and C implementations.

#### THE SOFA INITIATIVE

SOFA is an IAU Service which operates under Division 1 (Fundamental Astronomy) and reports through Commission 19 (Rotation of the Earth).

The IAU set up the SOFA initiative at the 1994 General Assembly, to promulgate an authoritative set of fundamental—astronomy constants and algorithms. At the subsequent General Assembly, in 1997, the appointment of a SOFA Review Board and the selection of a site for the SOFA Center (the outlet for SOFA products) were announced.

The SOFA initiative was originally proposed by the IAU Working Group on Astronomical Standards (WGAS), under the chairmanship of Toshio Fukushima. The proposal was for "...new arrangements to establish and maintain an accessible and authoritative set of constants, algorithms and procedures that implement standard models used in fundamental astronomy". The SOFA Software Libraries implement the "algorithms" part of the SOFA initiative. They were developed under the supervision of an international panel called the SOFA Review Board. The current membership of this panel is listed in an appendix.

A feature of the original SOFA software proposals was that the products would be self-contained and not depend on other software. This includes basic documentation, which, like the present file, will mostly be plain ASCII text. It should also be noted that there is no assumption that the software will be used on a particular computer and Operating System. Although OS-related facilities may be present (Unix make files for instance, use by the SOFA Center of automatic code management systems, HTML versions of some documentation), the routines themselves will be visible as individual text files and will run on a variety of platforms.

# ALGORITHMS

The SOFA Review Board's initial goal has been to create a set of callable subprograms. Whether "subroutines" or "functions", they are all referred to simply as "routines". They are designed for use by software developers wishing to write complete applications; no runnable, free-standing applications are included in SOFA's present plans.

The algorithms are drawn from a variety of sources. Because most of the routines so far developed have either been standard "text-book" operations or implement well-documented standard algorithms, it has not been necessary to invite the whole community to submit algorithms, though consultation with authorities has occurred where necessary. It should also be noted that consistency with the conventions published by the International Earth Rotation Service was a stipulation in the original SOFA proposals, further constraining the software designs. This state of affairs will continue to exist for some time, as there is a large backlog of agreed extensions to work on. However, in the future the Board may decide to call for proposals, and is in the meantime willing to look into any suggestions that are received by the SOFA Center.

SCOPE

The routines currently available are listed in the next two chapters of this document.

The "astronomy" library comprises 131 routines (plus one obsolete Fortran routine that now appears under a revised name). The areas addressed include calendars, time scales, ephemerides, precession-nutation, star space-motion, star catalog transformations and geodetic/geocentric transformations.

The "vector-matrix" library, comprising 55 routines, contains a collection of simple tools for manipulating the vectors, matrices and angles used by the astronomy routines.

There is no explicit commitment by SOFA to support historical models, though as time goes on a legacy of superseded models will naturally accumulate. There is, for example, no support of B1950/FK4 star coordinates, or pre-1976 precession models, though these capabilities could be added were there significant demand.

Though the SOFA software libraries are rather limited in scope, and are likely to remain so for a considerable time, they do offer distinct advantages to prospective users. In particular, the routines are:

- \* authoritative: they are IAU-backed and have been constructed with great care;
- \* practical: they are straightforward to use in spite of being precise and rigorous (to some stated degree);
- \* accessible and supported: they are downloadable from an easy-to-find place, they are in an integrated and consistent form, they come with adequate internal documentation, and help for users is available.

#### **VERSIONS**

Once it has been published, an issue is never revised or updated, and remains accessible indefinitely. Subsequent issues may, however, include corrected versions under the original routine name and filenames. However, where a different model is introduced, it will have a different name.

The issues will be referred to by the date when they were announced. The frequency of re-issue will be decided by the Board, taking into account the importance of the changes and the impact on the user community.

## DOCUMENTATION

At present there is little free-standing documentation about individual routines. However, each routine has preamble comments which specify in detail what the routine does and how it is used.

The file sofa\_pn.pdf describes the SOFA tools for precession-nutation and other aspects of Earth attitude and includes example code and (see the appendix) diagrams showing the interrelationships between the routines supporting the latest (IAU 2006/2000A) models.

# PROGRAMMING LANGUAGES AND STANDARDS

The SOFA routines are available in two programming languages at present: Fortran77 and ANSI C. Related software in other languages is under consideration.

The Fortran code conforms to ANSI X3.9-1978 in all but two minor respects: each has an IMPLICIT NONE declaration, and its name has a prefix of "iau\_" and may be longer than 6 characters. A global edit to erase both of these will produce ANSI-compliant code with no change in its function.

Coding style, and restrictions on the range of language features, have been much debated by the Board, and the results comply with the majority view. There is (at present) no document that defines the standards, but the code itself offers a wide range of examples of what is acceptable.

The Fortran routines contain explicit numerical constants (the INCLUDE statement is not part of ANSI Fortran77). These are drawn from the file consts.lis, which is listed in an appendix. Constants for the SOFA/C functions are defined in a header file sofam.h.

The naming convention is such that a SOFA routine referred to generically as "EXAMPL" exists as a Fortran subprogram iau\_EXAMPL and a C function iauExampl. The calls for the two versions are very similar, with the same arguments in the same order. In a few cases, the C equivalent of a Fortran SUBROUTINE subprogram uses a return value rather than an argument.

Each language version includes a "testbed" main-program that can be used to verify that the SOFA routines have been correctly compiled on the end user's system. The Fortran and C versions are called t\_sofa\_f.for and t\_sofa\_c.c respectively. The testbeds execute every SOFA routine and check that the results are within expected accuracy margins. It is not possible to guarantee that all platforms will meet the rather stringent criteria that have been used, and an occasional warning message may be encountered on some systems.

## COPYRIGHT ISSUES

Copyright for all of the SOFA software and documentation is owned by the IAU SOFA Review Board. The Software is made available free of charge for all classes of user, including commercial. However, there are strict rules designed to avoid unauthorized variants coming into circulation. It is permissible to distribute derived works and other modifications, but they must be clearly marked to avoid confusion with the SOFA originals.

Further details are included in the block of comments which concludes every routine. The text is also set out in an appendix to the present document.

# ACCURACY

The SOFA policy is to organize the calculations so that the machine accuracy is fully exploited. The gap between the precision of the underlying model or theory and the computational resolution has to be kept as large as possible, hopefully leaving several orders of magnitude of headroom.

The SOFA routines in some cases involve design compromises between rigor and ease of use (and also speed, though nowadays this is seldom a major concern).

# ACKNOWLEDGEMENTS

The Board is indebted to a number of contributors, who are acknowledged in the preamble comments of the routines concerned.

The Board's effort is provided by the members' individual institutes.

Resources for operating the SOFA Center are provided by Her Majesty's Nautical Almanac Office, operated by the United Kingdom Hydrographic Office.

# SOFA Astronomy Library

## PREFACE

The routines described here comprise the SOFA astronomy library. Their general appearance and coding style conforms to conventions agreed by the SOFA Review Board, and their functions, names and algorithms have been ratified by the Board. Procedures for soliciting and agreeing additions to the library are still evolving.

#### PROGRAMMING LANGUAGES

The SOFA routines are available in two programming languages at present: Fortran 77 and ANSI C.

Except for a single obsolete Fortran routine, which has no C equivalent, there is a one-to-one relationship between the two language versions. The naming convention is such that a SOFA routine referred to generically as "EXAMPL" exists as a Fortran subprogram iau\_EXAMPL and a C function iauExampl. The calls for the two versions are very similar, with the same arguments in the same order. In a few cases, the C equivalent of a Fortran SUBROUTINE subprogram uses a return value rather than an argument.

#### GENERAL PRINCIPLES

The principal function of the SOFA Astronomy Library is to provide definitive algorithms. A secondary function is to provide software suitable for convenient direct use by writers of astronomical applications.

The astronomy routines call on the SOFA vector/matrix library routines, which are separately listed.

The routines are designed to exploit the full floating-point accuracy of the machines on which they run, and not to rely on compiler optimizations. Within these constraints, the intention is that the code corresponds to the published formulation (if any).

Dates are always Julian Dates (except in calendar conversion routines) and are expressed as two double precision numbers which sum to the required value.

A distinction is made between routines that implement IAU-approved models and those that use those models to create other results. The former are referred to as "canonical models" in the preamble comments; the latter are described as "support routines".

Using the library requires knowledge of positional astronomy and time-scales. These topics are covered in "Explanatory Supplement to the Astronomical Almanac", P. Kenneth Seidelmann (ed.), University Science Books, 1992. Recent developments are documented in the journals, and references to the relevant papers are given in the SOFA code as required. The IERS Conventions are also an essential reference. The routines concerned with Earth attitude (precession-nutation etc.) are described in the SOFA document sofa\_pn.pdf.

```

# SOFA Vector/Matrix Library

#### PREFACE

The routines described here comprise the SOFA vector/matrix library. Their general appearance and coding style conforms to conventions agreed by the SOFA Review Board, and their functions, names and algorithms have been ratified by the Board. Procedures for soliciting and agreeing additions to the library are still evolving.

## PROGRAMMING LANGUAGES

The SOFA routines are available in two programming languages at present: Fortran 77 and ANSI C.

There is a one-to-one relationship between the two language versions. The naming convention is such that a SOFA routine referred to generically as "EXAMPL" exists as a Fortran subprogram iau\_EXAMPL and a C function iauExampl. The calls for the two versions are very similar, with the same arguments in the same order. In a few cases, the C equivalent of a Fortran SUBROUTINE subprogram uses a return value rather than an argument.

#### GENERAL PRINCIPLES

The library consists mostly of routines which operate on ordinary Cartesian vectors (x,y,z) and 3x3 rotation matrices. However, there is also support for vectors which represent velocity as well as position and vectors which represent rotation instead of position. The vectors which represent both position and velocity may be considered still to have dimensions (3), but to comprise elements each of which is two numbers, representing the value itself and the time derivative. Thus:

- \* "Position" or "p" vectors (or just plain 3-vectors) have dimension (3) in Fortran and [3] in C.
- \* "Position/velocity" or "pv" vectors have dimensions (3,2) in Fortran and [2][3] in C.
- \* "Rotation" or "r" matrices have dimensions (3,3) in Fortran and [3][3] in C. When used for rotation, they are "orthogonal"; the inverse of such a matrix is equal to the transpose. Most of the routines in this library do not assume that r-matrices are necessarily orthogonal and in fact work on any 3x3 matrix.
- \* "Rotation" or "r" vectors have dimensions (3) in Fortran and [3] in C. Such vectors are a combination of the Euler axis and angle and are convertible to and from r-matrices. The direction is the axis of rotation and the magnitude is the angle of rotation, in radians. Because the amount of rotation can be scaled up and down simply by multiplying the vector by a scalar, r-vectors are useful for representing spins about an axis which is fixed.
- \* The above rules mean that in terms of memory address, the three velocity components of a pv-vector follow the three position components. Application code is permitted to exploit this and all other knowledge of the internal layouts: that x, y and z appear in that order and are in a right-handed Cartesian coordinate system etc. For example, the cp function (copy a p-vector) can be used to copy the velocity component of a pv-vector (indeed, this is how the CPV routine is coded).
- \* The routines provided do not completely fill the range of operations that link all the various vector and matrix options, but are confined to functions that are required by other parts of the SOFA software or which are likely to prove useful.

In addition to the vector/matrix routines, the library contains some routines related to spherical angles, including conversions to and from sexagesimal format.

Using the library requires knowledge of vector/matrix methods, spherical trigonometry, and methods of attitude representation. These topics are covered in many textbooks, including "Spacecraft Attitude Determination and Control", James R. Wertz (ed.), Astrophysics and Space Science Library, Vol. 73, D. Reidel Publishing Company, 1986.

### OPERATIONS INVOLVING P-VECTORS AND R-MATRICES

### Initialize

```
ZΡ
          zero p-vector
```

initialize r-matrix to null ZR initialize r-matrix to identity

## Copy/extend/extract

CP copy p-vector CR copy r-matrix

#### Build rotations

RX	rotate	r-matrix	about	х
RY	rotate	r-matrix	about	У
RZ	rotate	r-matrix	about.	Z

#### Spherical/Cartesian conversions

spherical to unit vector
unit vector to spherical
spherical to p-vector
p-vector to spherical

## Operations on vectors

PPP	p-vector plus p-vector
PMP	p-vector minus p-vector
PPSP	p-vector plus scaled p-vector
PDP	inner (=scalar=dot) product of two p-vectors
DXD	outer (=vector=cross) product of two p-vector

outer (=vector=cross) product of two p-vectors

PMmodulus of p-vector

PNnormalize p-vector returning modulus

SXP multiply p-vector by scalar

# Operations on matrices

```
RXR
          r-matrix multiply
          transpose r-matrix
ΤR
```

# Matrix-vector products

```
RXP
```

product of r-matrix and p-vector
product of transpose of r-matrix and p-vector TRXP

# Separation and position-angle

SEPP	angular	separation	from	p-vectors
------	---------	------------	------	-----------

angular separation from spherical coordinates SEPS

PAP position-angle from p-vectors

position-angle from spherical coordinates PAS

# Rotation vectors

RV2M r-vector to r-matrix RM2V r-matrix to r-vector

## OPERATIONS INVOLVING PV-VECTORS

```
7.PV
                   zero pv-vector
  Copy/extend/extract
      CPV
                   copy pv-vector
      P2PV
                   append zero velocity to p-vector
      PV2P
                   discard velocity component of pv-vector
  Spherical/Cartesian conversions
      S2PV
                   spherical to pv-vector
                   pv-vector to spherical
      PV2S
  Operations on vectors
      MAdMd
                  pv-vector plus pv-vector
      PVMPV
                   pv-vector minus pv-vector
                   inner (=scalar=dot) product of two pv-vectors
      PVDPV
      VAXVA
                   outer (=vector=cross) product of two pv-vectors
      PVM
                   modulus of pv-vector
      SXPV
                   multiply pv-vector by scalar
      S2XPV
                  multiply pv-vector by two scalars
      PVU
                   update pv-vector
                   update pv-vector discarding velocity
      PVUP
  Matrix-vector products
                   product of r-matrix and pv-vector
      RXPV
      TRXPV
                   product of transpose of r-matrix and pv-vector
OPERATIONS ON ANGLES
      ANP
                   normalize radians to range 0 to 2pi
      ANPM
                   normalize radians to range -pi to +pi
      A2TF
                   decompose radians into hours, minutes, seconds

        3
* *
                       0 00 00.000...
* *
    2) The largest positive useful value for ndp is determined by the
* *
        size of angle, the format of doubles on the target platform, and
       the risk of overflowing idmsf[3]. On a typical platform, for angle up to 2pi, the available floating-point precision might
* *
* *
* *
        correspond to ndp=12. However, the practical limit is typically
* *
       ndp=9, set by the capacity of a 32-bit int, or ndp=4 if int is
* *
       only 16 bits.
```

3) The absolute value of angle may exceed 2pi. In cases where it does not, it is up to the caller to test for and handle the

by testing for idmsf[0]=360 and setting idmsf[0-3] to zero.

case where angle is very nearly 2pi and rounds up to 360 degrees,

\* \*

* *
                        0 00 00.000...
* *
    2) The largest positive useful value for ndp is determined by the
* *
        size of angle, the format of doubles on the target platform, and
       the risk of overflowing ihmsf[3]. On a typical platform, for angle up to 2pi, the available floating-point precision might
* *
* *
* *
        correspond to ndp=12. However, the practical limit is typically
```

ndp=9, set by the capacity of a 32-bit int, or ndp=4 if int is

case where angle is very nearly 2pi and rounds up to 24 hours,

3) The absolute value of angle may exceed 2pi. In cases where it does not, it is up to the caller to test for and handle the

by testing for ihmsf[0]=24 and setting ihmsf(0-3) to zero.

\* \*

\* \*

\* \*

\* \* \* \*

\* \*

\* \* \* / only 16 bits.

```
int iauAf2a(char s, int ideg, int iamin, double asec, double *rad)
* *
    iau Af2a
* *
* *
* *
   Convert degrees, arcminutes, arcseconds to radians.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
   Status: support function.
* *
* *
    Given:
* *
                         sign: '-' = negative, otherwise positive
                 char
      S
* *
       ideg
                 int
                          degrees
* *
       iamin
                 int
                          arcminutes
* *
                 double arcseconds
       asec
* *
* *
    Returned:
* *
      rad
                 double angle in radians
* *
* *
    Returned (function value):
* *
                        status: 0 = OK
                 int
* *
                                   1 = ideg outside range 0-359
* *
                                    2 = iamin outside range 0-59
* *
                                    3 = asec outside range 0-59.999...
* *
* *
   Notes:
* *
* *
    1) The result is computed even if any of the range checks fail.
* *
* *
    2) Negative ideg, iamin and/or asec produce a warning status, but
* *
        the absolute value is used in the conversion.
* *
* *
    3) If there are multiple errors, the status value reflects only the
* *
        first, the smallest taking precedence.
* *

```

```
void iauBi00(double *dpsibi, double *depsbi, double *dra)
* *
     iauBi00
* *
* *
* *
    Frame bias components of IAU 2000 precession-nutation models (part
* *
    of MHB2000 with additions).
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Returned:
* *
        dpsibi,depsbi double longitude and obliquity corrections dra double the ICRS RA of the J2000.0 mean equinox
* *
* *
* *
    Notes:
* *
* *
    1) The frame bias corrections in longitude and obliquity (radians)
        are required in order to correct for the offset between the GCRS pole and the mean J2000.0 pole. They define, with respect to the GCRS frame, a J2000.0 mean pole that is consistent with the rest
* *
* *
* *
* *
        of the IAU 2000A precession-nutation model.
* *
* *
    2) In addition to the displacement of the pole, the complete
* *
        description of the frame bias requires also an offset in right
* *
        ascension. This is not part of the IAU 2000A model, and is from
* *
        Chapront et al. (2002). It is returned in radians.
* *
* *
    3) This is a supplemented implementation of one aspect of the IAU
* *
        2000A nutation model, formally adopted by the IAU General
* *
        Assembly in 2000, namely MHB2000 (Mathews et al. 2002).
* *

* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
* *
           2451545.0
                            -1421.3
                                            (J2000 method)
* *
           2400000.5
                            50123.2
                                            (MJD method)
* *
           2450123.5
                                 0.2
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix rb transforms vectors from GCRS to mean J2000.0 by
* *
       applying frame bias.
* *
* *
    3) The matrix rp transforms vectors from J2000.0 mean equator and
* *
       equinox to mean equator and equinox of date by applying
* *
       precession.
* *
* *
    4) The matrix rbp transforms vectors from GCRS to mean equator and
* *
       equinox of date by applying frame bias then precession. It is
* *
       the product rp x rb.
* *
* *
    5) It is permissible to re-use the same array in the returned
* *
       arguments. The arrays are filled in the order given.

* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix rc2i is the first stage in the transformation from
* *
       celestial to terrestrial coordinates:
* *
* *
          [TRS] = RPOM * R_3(ERA) * rc2i * [CRS]
* *
* *
                  = rc2t * [CRS]
* *
* *
       where [CRS] is a vector in the Geocentric Celestial Reference
* *
       System and [TRS] is a vector in the International Terrestrial
* *
       Reference System (see IERS Conventions 2003), ERA is the Earth
* *
       Rotation Angle and RPOM is the polar motion matrix.
* *
* *
    3) A faster, but slightly less accurate result (about 1 mas), can be
* *
       obtained by using instead the iauC2i00b function.
* *
* *
    Called:
* *
       iauPnm00a
                     classical NPB matrix, IAU 2000A
* *
       iauC2ibpn
                     celestial-to-intermediate matrix, given NPB matrix
* *
* *
    References:

* *
       Ephemeris Origin consistent with the IAU 2000A precession-
* *
       nutation model", Astron. Astrophys. 400, 1145-1154
* *
       (2003)
* *
```

n.b. The celestial ephemeris origin (CEO) was renamed "celestial

intermediate origin" (CIO) by IAU 2006 Resolution 2.

McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003),

\* \*

\* \*

\* \*

```
** IERS Technical Note No. 32, BKG (2004) **
```

```
void iauC2i00b(double date1, double date2, double rc2i[3][3])
* *
     iauC2i00b
* *
* *
* *
    Form the celestial-to-intermediate matrix for a given date using the
* *
    IAU 2000B precession-nutation model.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       date1,date2 double
                                TT as a 2-part Julian Date (Note 1)
* *
* *
    Returned:
* *
                    double[3][3] celestial-to-intermediate matrix (Note 2)
       rc2i
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
                            -1421.3
* *
                                           (J2000 method)
           2451545.0
* *
           2400000.5
                            50123.2
                                           (MJD method)
* *
           2450123.5
                                           (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix rc2i is the first stage in the transformation from
* *
       celestial to terrestrial coordinates:
* *
* *
          [TRS] = RPOM * R_3(ERA) * rc2i * [CRS]
* *
* *
                  = rc2t * [CRS]
* *
* *
       where [CRS] is a vector in the Geocentric Celestial Reference
* *
       System and [TRS] is a vector in the International Terrestrial
* *
       Reference System (see IERS Conventions 2003), ERA is the Earth
* *
       Rotation Angle and RPOM is the polar motion matrix.
* *
* *
    3) The present function is faster, but slightly less accurate (about
* *
       1 mas), than the iauC2i00a function.
* *
* *
    Called:
* *
       iauPnm00b
                     classical NPB matrix, IAU 2000B
* *
       iauC2ibpn
                     celestial-to-intermediate matrix, given NPB matrix
* *
* *
    References:
* *
* *
       "Expressions for the Celestial Intermediate Pole and Celestial
* *
       Ephemeris Origin consistent with the IAU 2000A precession-
* *
       nutation model", Astron. Astrophys. 400, 1145-1154
* *
       (2003)
* *
```

n.b. The celestial ephemeris origin (CEO) was renamed "celestial

intermediate origin" (CIO) by IAU 2006 Resolution 2.

\* \*

\* \*

\* \*

\* \*

\* \*

\* \*

Returned:

rc2i double[3][3] celestial-to-intermediate matrix (Note 3)

\*\* Notes:

1) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others:

	date2	date1
(JD method)	0.0	2450123.7
(J2000 method)	-1421.3	2451545.0
(MJD method)	50123.2	2400000.5
(date & time method)	0.2	2450123.5

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

- 2) The matrix rbpn transforms vectors from GCRS to true equator (and CIO or equinox) of date. Only the CIP (bottom row) is used.
- 3) The matrix rc2i is the first stage in the transformation from celestial to terrestrial coordinates:

```
[TRS] = RPOM * R_3(ERA) * rc2i * [CRS]
= RC2T * [CRS]
```

where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), ERA is the Earth Rotation Angle and RPOM is the polar motion matrix.

4) Although its name does not include "00", This function is in fact specific to the IAU 2000 models.

\* \* \* \*

\* \*

tta,ttb double TT as a 2-part Julian Date (Note 1)
uta,utb double UT1 as a 2-part Julian Date (Note 1)
xp,yp double coordinates of the pole (radians, Note 2)

\*\* Returned:

rc2t double[3][3] celestial-to-terrestrial matrix (Note 3)

Notes:

1) The TT and UT1 dates tta+ttb and uta+utb are Julian Dates, apportioned in any convenient way between the arguments uta and utb. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others:

uta utb

2450123.7 0.0
2451545.0 -1421.3
2400000.5 50123.2

(JD method) (J2000 method) (MJD method)

(date & time method)

2400000.5 50123.2 2450123.5 0.2

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. In the case of uta,utb, the date & time method is best matched to the Earth rotation angle algorithm used: maximum precision is delivered when the uta argument is for Ohrs UT1 on the day in question and the utb argument lies in the range 0 to 1, or vice versa.

- 2) The arguments xp and yp are the coordinates (in radians) of the Celestial Intermediate Pole with respect to the International Terrestrial Reference System (see IERS Conventions 2003), measured along the meridians to 0 and 90 deg west respectively.
- 3) The matrix rc2t transforms from celestial to terrestrial coordinates:

```
[TRS] = RPOM * R_3(ERA) * RC2I * [CRS]
= rc2t * [CRS]
```

where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), RC2I is the celestial-to-intermediate matrix, ERA is the Earth rotation angle and RPOM is the polar motion matrix.

4) A faster, but slightly less accurate result (about 1 mas), can be obtained by using instead the iauC2t00b function.

tta,ttb double TT as a 2-part Julian Date (Note 1)
uta,utb double UT1 as a 2-part Julian Date (Note 1)
xp,yp double coordinates of the pole (radians, Note 2)

\*\* Returned:

rc2t double[3][3] celestial-to-terrestrial matrix (Note 3)

Notes:

1) The TT and UT1 dates tta+ttb and uta+utb are Julian Dates, apportioned in any convenient way between the arguments uta and utb. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others:

uta utb
2450123.7 0.0
2451545.0 -1421.3

0.0 (JD method) -1421.3 (J2000 method) 50123.2 (MJD method)

2450123.5 0.2

(date & time method)

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. In the case of uta,utb, the date & time method is best matched to the Earth rotation angle algorithm used: maximum precision is delivered when the uta argument is for Ohrs UT1 on the day in question and the utb argument lies in the range 0 to 1, or vice versa.

- 2) The arguments xp and yp are the coordinates (in radians) of the Celestial Intermediate Pole with respect to the International Terrestrial Reference System (see IERS Conventions 2003), measured along the meridians to 0 and 90 deg west respectively.
- 3) The matrix rc2t transforms from celestial to terrestrial coordinates:

```
[TRS] = RPOM * R_3(ERA) * RC2I * [CRS]
= rc2t * [CRS]
```

where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), RC2I is the celestial-to-intermediate matrix, ERA is the Earth rotation angle and RPOM is the polar motion matrix.

4) The present function is faster, but slightly less accurate (about 1 mas), than the iauC2t00a function.

* *
    1) This function constructs the rotation matrix that transforms
* *
       vectors in the celestial system into vectors in the terrestrial
* *
       system. It does so starting from precomputed components, namely
* *
       the matrix which rotates from celestial coordinates to the
       intermediate frame, the Earth rotation angle and the polar motion matrix. One use of the present function is when generating a
* *
* *
* *
       series of celestial-to-terrestrial matrices where only the Earth
* *
       Rotation Angle changes, avoiding the considerable overhead of
* *
       recomputing the precession-nutation more often than necessary to
* *
       achieve given accuracy objectives.
* *
* *
    2) The relationship between the arguments is as follows:
* *
* *
          [TRS] = RPOM * R_3(ERA) * rc2i * [CRS]
* *
* *
                 = rc2t * [CRS]
* *
       where [CRS] is a vector in the Geocentric Celestial Reference
* *
       System and [TRS] is a vector in the International Terrestrial
* *
       Reference System (see IERS Conventions 2003).

\*\* Returned:

rc2t double[3][3] celestial-to-terrestrial matrix (Note 4)

## Notes:

1) The TT and UT1 dates tta+ttb and uta+utb are Julian Dates, apportioned in any convenient way between the arguments uta and utb. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others:

uta	utb	
2450123.7	0.0	(JD method)
2451545.0	-1421.3	(J2000 method)
2400000.5	50123.2	(MJD method)
2450123.5	0.2	(date & time method)

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. In the case of uta,utb, the date & time method is best matched to the Earth rotation angle algorithm used: maximum precision is delivered when the uta argument is for Ohrs UT1 on the day in question and the utb argument lies in the range 0 to 1, or vice versa.

- 2) The caller is responsible for providing the nutation components; they are in longitude and obliquity, in radians and are with respect to the equinox and ecliptic of date. For high-accuracy applications, free core nutation should be included as well as any other relevant corrections to the position of the CIP.
- 3) The arguments xp and yp are the coordinates (in radians) of the Celestial Intermediate Pole with respect to the International Terrestrial Reference System (see IERS Conventions 2003), measured along the meridians to 0 and 90 deg west respectively.
- 4) The matrix rc2t transforms from celestial to terrestrial coordinates:

```
[TRS] = RPOM * R_3(GST) * RBPN * [CRS]
= rc2t * [CRS]
```

where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), RBPN is the bias-precession-nutation matrix, GST is the Greenwich (apparent) Sidereal Time and RPOM is the polar motion matrix.

```
5) Although its name does not include "00", This function is in fact specific to the IAU 2000 models.

    Given:
* *
       iy,im,id int
                         year, month, day in Gregorian calendar (Note 1)
* *
* *
    Returned:
                  double MJD zero-point: always 2400000.5 double Modified Julian Date for 0 hrs
* *
       djm0
* *
       dim
* *
* *
    Returned (function value):
* *
                  int
                           status:
* *
                               0 = OK
* *
                              -1 = bad year
                                               (Note 3: JD not computed)
* *
                              -2 = bad month (JD not computed)
* *
                              -3 = bad day
                                               (JD computed)
* *
* *
    Notes:
* *
* *
    1) The algorithm used is valid from -4800 March 1, but this
* *
       implementation rejects dates before -4799 January 1.
* *
* *
    2) The Julian Date is returned in two pieces, in the usual SOFA
* *
       manner, which is designed to preserve time resolution. The
* *
       Julian Date is available as a single number by adding djm0 and
* *
       djm.
* *
* *
    3) In early eras the conversion is from the "Proleptic Gregorian
* *
       Calendar"; no account is taken of the date(s) of adoption of
* *
       the Gregorian Calendar, nor is the AD/BC numbering convention
* *
       observed.
* *

* *
* *
     iauD2dtf
* *
* *
* *
    Format for output a 2-part Julian Date (or in the case of UTC a
* *
    quasi-JD form that includes special provision for leap seconds).
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
                  char[] time scale ID (Note 1)
       scale
* *
       ndp
                          resolution (Note 2)
                  int
* *
       d1,d2
                  double time as a 2-part Julian Date (Notes 3,4)
* *
* *
    Returned:
* *
       iy,im,id int
                          year, month, day in Gregorian calendar (Note 5)
* *
                  int[4] hours, minutes, seconds, fraction (Note 1)
       ihmsf
* *
* *
    Returned (function value):
* *
                          status: +1 = dubious year (Note 5)
                  int
* *
                                   0 = OK
* *
                                   -1 = unacceptable date (Note 6)
* *
* *
    Notes:
* *
* *
    1) scale identifies the time scale. Only the value "UTC" (in upper
* *
       case) is significant, and enables handling of leap seconds (see
* *
       Note 4).
* *
* *
    2) ndp is the number of decimal places in the seconds field, and can
* *
       have negative as well as positive values, such as:
* *
* *
                    resolution
       ndp
* *
                      1 00 00
       -4
* *
                      0 10 00
       -3
* *
       -2
                      0 01 00
* *
       -1
                      0 00 10
* *
                      0 00 01
        Ω
* *
        1
                      0 00 00.1
* *
        2
                      0 00 00.01
* *
                      0 00 00.001
* *
* *
       The limits are platform dependent, but a safe range is -5 to +9.
* *
* *
    3) d1+d2 is Julian Date, apportioned in any convenient way between
       the two arguments, for example where d1 is the Julian Day Number
* *
       and d2 is the fraction of a day. In the case of UTC, where the
* *
* *
       use of JD is problematical, special conventions apply: see the
* *
       next note.
* *
* *
    4) JD cannot unambiguously represent UTC during a leap second unless
       special measures are taken. The SOFA internal convention is that the quasi-JD day represents UTC days whether the length is 86399,
* *
* *
* *
       86400 or 86401 SI seconds.
* *
* *
    5) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
* *
       to be trusted. See iauDat for further details.
* *
* *
    6) For calendar conventions and limitations, see iauCal2jd.
* *
* *
    Called:
* *
       iauJd2cal
                     JD to Gregorian calendar
* *
       iauD2tf
                     decompose days to hms
* *
                     delta(AT) = TAI-UTC
       iauDat
```

```
void iauD2tf(int ndp, double days, char *sign, int ihmsf[4])
* *
    iauD2tf
* *
* *
* *
    Decompose days to hours, minutes, seconds, fraction.
* *
    This function is part of the International Astronomical Union's
* *
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                int
                       resolution (Note 1)
      ndp
* *
               double interval in days
       days
* *
* *
    Returned:
* *
                        '+' or '-'
                char
       sian
* *
                int[4] hours, minutes, seconds, fraction
       ihmsf
* *
* *
    Notes:
* *
* *
    1) The argument ndp is interpreted as follows:
* *
* *
       ndp
                   resolution
* *
                ...0000 00 00
       :
* *
       -7
                  1000 00 00
                    100 00 00
* *
       -6
* *
                    10 00 00
       -5
* *
       -4
                      1 00 00
* *
                     0 10 00
       -3
* *
       -2
                     0 01 00
* *
       -1
                      0 00 10
* *
                      0 00 01
       0
* *
       1
                      0 00 00.1
* *
        2
                      0 00 00.01
* *
                      0 00 00.001
        3
* *
                      0 00 00.000...
* *
    2) The largest positive useful value for ndp is determined by the
* *
       size of days, the format of double on the target platform, and
* *
       the risk of overflowing ihmsf[3]. On a typical platform, for
       days up to 1.0, the available floating-point precision might
* *
       correspond to ndp=12. However, the practical limit is typically
       ndp=9, set by the capacity of a 32-bit int, or ndp=4 if int is
* *
* *
       only 16 bits.
```

3) The absolute value of days may exceed 1.0. In cases where it

by testing for ihmsf[0]=24 and setting ihmsf[0-3] to zero.

does not, it is up to the caller to test for and handle the

case where days is very nearly 1.0 and rounds up to 24 hours,

\* \* \* \*

\* \*

\* \*

\* \*

\* \* \* /

```
* *
    iauDat
* *
* *
* *
   For a given UTC date, calculate delta(AT) = TAI-UTC.
* *
* *
* *
* *
                          IMPORTANT
* *
* *
       : A new version of this function must be
* *
          produced whenever a new leap second is
* *
         announced. There are four items to
* *
          change on each such occasion:
* *
* *
          1) A new line must be added to the set
* *
           of statements that initialize the
       :
* *
             array "changes".
* *
* *
          2) The parameter IYV must be set to
* *
             the current year.
* *
* *
          3) The "Latest leap second" comment
* *
             below must be set to the new leap
* *
             second date.
* *
* *
         4) The "This revision" comment, later,
* *
             must be set to the current date.
* *
* *
       : Change (2) must also be carried out
* *
         whenever the function is re-issued,
* *
          even if no leap seconds have been
* *
          added.
* *
* *
       : Latest leap second: 2012 June 30
* *
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
    Status: support function.
* *
* *
    Given:
* *
              int
                        UTC: year (Notes 1 and 2)
       iу
* *
              int
       im
                              month (Note 2)
* *
       id
              int
                               day (Notes 2 and 3)
* *
                              fraction of day (Note 4)
              double
       fd
* *
* *
    Returned:
* *
       deltat double TAI minus UTC, seconds
* *
* *
    Returned (function value):
* *
                       status (Note 5):
              int
* *
                          1 = dubious year (Note 1)
* *
                          0 = OK
* *
                         -1 = bad year
* *
                         -2 = bad month
                         -3 = bad day (Note 3)
-4 = bad fraction (Note 4)
* *
* *
* *
* *
    Notes:
* *
* *
    1) UTC began at 1960 January 1.0 (JD 2436934.5) and it is improper
* *
       to call the function with an earlier date. If this is attempted,
* *
       zero is returned together with a warning status.
* *
* *
       Because leap seconds cannot, in principle, be predicted in
       advance, a reliable check for dates beyond the valid range is
```

int iauDat(int iy, int im, int id, double fd, double \*deltat )

impossible. To guard against gross errors, a year five or more after the release year of the present function (see parameter IYV) is considered dubious. In this case a warning status is returned but the result is computed in the normal way.

\* \* \* \* \* \*

\* \*

\* \*

For both too-early and too-late years, the warning status is j=+1. This is distinct from the error status j=-1, which signifies a year so early that JD could not be computed.

\* \* \* \* \* \*

\* \*

2) If the specified date is for a day which ends with a leap second, the UTC-TAI value returned is for the period leading up to the leap second. If the date is for a day which begins as a leap second ends, the UTC-TAI returned is for the period following the leap second.

\* \* \* \* \* \*

\* \*

3) The day number must be in the normal calendar range, for example 1 through 30 for April. The "almanac" convention of allowing such dates as January 0 and December 32 is not supported in this function, in order to avoid confusion near leap seconds.

\* \* \* \* \* \*

\* \*

\* \*

\* \*

4) The fraction of day is used only for dates before the introduction of leap seconds, the first of which occurred at the end of 1971. It is tested for validity (0 to 1 is the valid range) even if not used; if invalid, zero is used and status j=-4 is returned. For many applications, setting fd to zero is acceptable; the resulting error is always less than 3 ms (and occurs only pre-1972).

\* \* \* \* \* \*

> \* \* \* \*

5) The status value returned in the case where there are multiple errors refers to the first error detected. For example, if the month and day are 13 and 32 respectively, j=-2 (bad month) will be returned.

\* \* \* \* \* \*

6) In cases where a valid result is not available, zero is returned.

\*\* References:

\* \*

\*\* 1) For dates from 1961 January 1 onwards, the expressions from the
\*\* file ftp://maia.usno.navy.mil/ser7/tai-utc.dat are used.

\* \* \* \*

2) The 5ms timestep at 1961 January 1 is taken from 2.58.1 (p87) of the 1992 Explanatory Supplement.

* *
* *
    Notes:
* *
* *
    1) The date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                               date2
* *
* *
            2450123.7
                                 0.0
                                            (JD method)
                             -1421.3
* *
                                            (J2000 method)
            2451545.0
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
            2450123.5
                                 0.2
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
```

cases where the loss of several decimal digits of resolution

is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

\* \* \* \* \* \*

Although the date is, formally, barycentric dynamical time (TDB), the terrestrial dynamical time (TT) can be used with no practical effect on the accuracy of the prediction.

\* \* \* \* \* \*

\* \*

\* \*

2) TT can be regarded as a coordinate time that is realized as an offset of 32.184s from International Atomic Time, TAI. TT is a specific linear transformation of geocentric coordinate time TCG, which is the time scale for the Geocentric Celestial Reference System, GCRS.

\* \* \* \* \* \* \* \*

3) TDB is a coordinate time, and is a specific linear transformation of barycentric coordinate time TCB, which is the time scale for the Barycentric Celestial Reference System, BCRS.

\* \* \* \* \* \*

\* \*

\* \*

\* \*

\* \*

\* \* \* \*

\* \*

\* \*

4) The difference TCG-TCB depends on the masses and positions of the bodies of the solar system and the velocity of the Earth. It is dominated by a rate difference, the residual being of a periodic character. The latter, which is modeled by the present function, comprises a main (annual) sinusoidal term of amplitude approximately 0.00166 seconds, plus planetary terms up to about 20 microseconds, and lunar and diurnal terms up to 2 microseconds. These effects come from the changing transverse Doppler effect and gravitational red-shift as the observer (on the Earth's surface) experiences variations in speed (with respect to the BCRS) and gravitational potential.

\* \* \* \* \* \*

\* \*

\* \* \* \*

\* \*

\* \*

\* \*

5) TDB can be regarded as the same as TCB but with a rate adjustment to keep it close to TT, which is convenient for many applications. The history of successive attempts to define TDB is set out in Resolution 3 adopted by the IAU General Assembly in 2006, which defines a fixed TDB(TCB) transformation that is consistent with contemporary solar-system ephemerides. Future ephemerides will imply slightly changed transformations between TCG and TCB, which could introduce a linear drift between TDB and TT; however, any such drift is unlikely to exceed 1 nanosecond per century.

\* \* \* \*

\* \*

\* \*

\* \*

\* \*

6) The geocentric TDB-TT model used in the present function is that of Fairhead & Bretagnon (1990), in its full form. It was originally supplied by Fairhead (private communications with P.T.Wallace, 1990) as a Fortran subroutine. The present C function contains an adaptation of the Fairhead code. The numerical results are essentially unaffected by the changes, the differences with respect to the Fairhead & Bretagnon original being at the 1e-20 s level.

\* \* \* \* \* \*

\* \*

\* \*

The topocentric part of the model is from Moyer (1981) and Murray (1983), with fundamental arguments adapted from Simon et al. 1994. It is an approximation to the expression (  $v\ /\ c$  ) . (  $r\ /\ c$  ), where v is the barycentric velocity of the Earth, r is the geocentric position of the observer and c is the speed of light.

\* \* \* \* \* \* \* \*

By supplying zeroes for u and v, the topocentric part of the model can be nullified, and the function will return the Fairhead & Bretagnon result alone.

\* \* \* \* \* \*

\* \*

\* \*

\* \*

7) During the interval 1950-2050, the absolute accuracy is better than +/- 3 nanoseconds relative to time ephemerides obtained by direct numerical integrations based on the JPL DE405 solar system ephemeris.

\* \* \* \* \* \* 8) It must be stressed that the present function is merely a model, and that numerical integration of solar-system ephemerides is the definitive method for predicting the relationship between TCG and TCB and hence between TT and TDB.

                  int
* *
                                     +2 = time is after end of day (Note 5)
* *
                                     +1 = dubious year (Note 6)
* *
                                     0 = OK
* *
                                    -1 = bad year
* *
                                     -2 = bad month
* *
                                     -3 = bad day
* *
                                     -4 = bad hour
* *
                                    -5 = bad minute
* *
                                     -6 = bad second (<0)
* *
* *
    Notes:
* *
    1) scale identifies the time scale. Only the value "UTC" (in upper case) is significant, and enables handling of leap seconds (see
* *
* *
* *
    2) For calendar conventions and limitations, see iauCal2jd.
* *
    3) The sum of the results, d1+d2, is Julian Date, where normally d1 is the Julian Day Number and d2 is the fraction of a day. In th
* *
* *
* *
       case of UTC, where the use of JD is problematical, special
* *
       conventions apply: see the next note.
* *
* *
    4) JD cannot unambiguously represent UTC during a leap second unless
       special measures are taken. The SOFA internal convention is that
* *
       the quasi-JD day represents UTC days whether the length is 86399,
* *
* *
       86400 or 86401 SI seconds.
* *
* *
    5) The warning status "time is after end of day" usually means that
* *
       the sec argument is greater than 60.0. However, in a day ending
* *
       in a leap second the limit changes to 61.0 (or 59.0 in the case
* *
       of a negative leap second).
* *
* *
    6) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
* *
       to be trusted. See iauDat for further details.
* *
* *
    7) Only in the case of continuous and regular time scales (TAI, TT,
* *
       TCG, TCB and TDB) is the result d1+d2 a Julian Date, strictly
* *
       speaking. In the other cases (UT1 and UTC) the result must be
* *
       used with circumspection; in particular the difference between
* *
       two such results cannot be interpreted as a precise time
* *
       interval.

* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                               date2
* *
* *
            2450123.7
                                 0.0
                                            (JD method)
* *
            2451545.0
                             -1421.3
                                            (J2000 method)
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
            2450123.5
                                 0.2
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The obliquity, in radians, is mean of date.
* *
* *
    3) The result, which is in radians, operates in the following sense:
* *
* *
          Greenwich apparent ST = GMST + equation of the equinoxes
* *
    4) The result is compatible with the IAU 2000 resolutions. For
* *
       further details, see IERS Conventions 2003 and Capitaine et al.
* *
       (2002).

double iauEe00b(double date1, double date2)
* *
     iauEe00b
* *
* *
* *
    Equation of the equinoxes, compatible with IAU 2000 resolutions but
* *
    using the truncated nutation model IAU 2000B.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
                                 TT as a 2-part Julian Date (Note 1)
       date1,date2 double
* *
* *
    Returned (function value):
* *
                                equation of the equinoxes (Note 2)
                      double
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                                date2
* *
* *
            2450123.7
                                  0.0
                                             (JD method)
                              -1421.3
* *
                                             (J2000 method)
            2451545.0
* *
            2400000.5
                              50123.2
                                             (MJD method)
* *
            2450123.5
                                             (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The result, which is in radians, operates in the following sense:
* *
* *
           Greenwich apparent ST = GMST + equation of the equinoxes
* *
* *
    3) The result is compatible with the IAU 2000 resolutions except
* *
       that accuracy has been compromised for the sake of speed. For
* *
       further details, see McCarthy & Luzum (2001), IERS Conventions
* *
       2003 and Capitaine et al. (2003).

* *
           2451545.0
                                           (J2000 method)
* *
           2400000.5
                            50123.2
                                           (MJD method)
* *
           2450123.5
                                           (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The "complementary terms" are part of the equation of the
* *
       equinoxes (EE), classically the difference between apparent and
* *
       mean Sidereal Time:
* *
* *
          GAST = GMST + EE
* *
* *
       with:
* *
* *
          EE = dpsi * cos(eps)
* *
* *
       where dpsi is the nutation in longitude and eps is the obliquity
* *
       of date. However, if the rotation of the Earth were constant in
* *
       an inertial frame the classical formulation would lead to
* *
       apparent irregularities in the UT1 timescale traceable to side-
* *
       effects of precession-nutation. In order to eliminate these
* *
       effects from UT1, "complementary terms" were introduced in 1994
* *
       (IAU, 1994) and took effect from 1997 (Capitaine and Gontier,
* *
       1993):
* *
* *
          GAST = GMST + CT + EE
* *
* *
       By convention, the complementary terms are included as part of
* *
       the equation of the equinoxes rather than as part of the mean
* *
       Sidereal Time. This slightly compromises the "geometrical"
* *
       interpretation of mean sidereal time but is otherwise
* *
       inconsequential.
```

The present function computes CT in the above expression,

IERS Conventions 2003).

compatible with IAU 2000 resolutions (Capitaine et al., 2002, and

int iauEform ( int n, double *a, double *f )
* *
     iauEform
* *
* *
* *
    Earth reference ellipsoids.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical.
* *
* *
    Given:
* *
                          ellipsoid identifier (Note 1)
      n
             int
* *
* *
    Returned:
* *
            double
                          equatorial radius (meters, Note 2)
* *
                          flattening (Note 2)
            double
* *
* *
    Returned (function value):
* *
                          status: 0 = OK
             int
* *
                                   -1 = illegal identifier (Note 3)
* *
* *
    Notes:
* *
* *
    1) The identifier n is a number that specifies the choice of
* *
       reference ellipsoid. The following are supported:
* *
* *
                ellipsoid
* *
* *
                 WGS84
           1
* *
                 GRS80
* *
                 WGS72
* *
* *
       The n value has no significance outside the SOFA software. For
* *
       convenience, symbols WGS84 etc. are defined in sofam.h.
* *
* *
    2) The ellipsoid parameters are returned in the form of equatorial
       radius in meters (a) and flattening (f). The latter is a number around 0.00335, i.e. around 1/298.
* *
* *
* *
* *
    3) For the case where an unsupported n value is supplied, zero a and
       f are returned, as well as error status.
* *

* *
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
      date1,date2 double
                               TT as a 2-part Julian Date (Note 1)
* *
* *
    Returned (function value):
* *
                     double
                               equation of the origins in radians
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
* *
           2451545.0
                            -1421.3
                                           (J2000 method)
* *
           2400000.5
                            50123.2
                                           (MJD method)
* *
           2450123.5
                                0.2
                                           (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The equation of the origins is the distance between the true
* *
       equinox and the celestial intermediate origin and, equivalently,
* *
       the difference between Earth rotation angle and Greenwich
* *
       apparent sidereal time (ERA-GST). It comprises the precession
* *
       (since J2000.0) in right ascension plus the equation of the
* *
       equinoxes (including the small correction terms).

```

```
double iauEors(double rnpb[3][3], double s)
* *
    iauEors
* *
* *
    Equation of the origins, given the classical NPB matrix and the
* *
    quantity s.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       rnpb double[3][3] classical nutation x precession x bias matrix
* *
             double
                            the quantity s (the CIO locator)
* *
* *
   Returned (function value):
* *
             double
                            the equation of the origins in radians.
* *
* *
    Notes:
* *
* *
    1) The equation of the origins is the distance between the true
* *
        equinox and the celestial intermediate origin and, equivalently,
* *
        the difference between Earth rotation angle and Greenwich
* *
        apparent sidereal time (ERA-GST). It comprises the precession
* *
        (since J2000.0) in right ascension plus the equation of the
* *
        equinoxes (including the small correction terms).
* *
* *
    2) The algorithm is from Wallace & Capitaine (2006).
* *

    Earth position and velocity, heliocentric and barycentric, with
* *
    respect to the Barycentric Celestial Reference System.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       date1,date2 double
                                    TDB date (Note 1)
* *
* *
    Returned:
       pvh
* *
                     double[2][3] heliocentric Earth position/velocity
                     double[2][3] barycentric Earth position/velocity
* *
       pvb
* *
* *
    Returned (function value):
* *
                                    status: 0 = OK
                     int
* *
                                           +1 = warning: date outside
* *
                                                 the range 1900-2100 AD
* *
* *
    Notes:
* *
    1) The TDB date date1+date2 is a Julian Date, apportioned in any
* *
* *
       convenient way between the two arguments. For example,
* *
       JD(TDB)=2450123.7 could be expressed in any of these ways, among
* *
       others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                 0.0
                                           (JD method)
* *
           2451545.0
                            -1421.3
                                            (J2000 method)
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
           2450123.5
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in cases
* *
       where the loss of several decimal digits of resolution is
       acceptable. The J2000 method is best matched to the way the
* *
       argument is handled internally and will deliver the optimum
* *
       resolution. The MJD method and the date & time methods are both
* *
       good compromises between resolution and convenience. However,
* *
       the accuracy of the result is more likely to be limited by the
* *
       algorithm itself than the way the date has been expressed.
* *
* *
       n.b. TT can be used instead of TDB in most applications.
* *
* *
    2) On return, the arrays pvh and pvb contain the following:
* *
* *
          pvh[0][0]
* *
          pvh[0][1]
                                 heliocentric position, AU
                      У
* *
          pvh[0][2] z
* *
* *
          pvh[1][0] xdot
* *
          pvh[1][1]
                      ydot
                                heliocentric velocity, AU/d
* *
          pvh[1][2]
                      zdot
* *
* *
          pvb[0][0]
                      X
* *
          pvb[0][1]
                                 barycentric position, AU
                      У
* *
          pvb[0][2]
* *
* *
          pvb[1][0]
                      xdot
* *
          pvb[1][1]
                      ydot
                                 barycentric velocity, AU/d
* *
          pvb[1][2]
                     zdot
* *
```

The vectors are with respect to the Barycentric Celestial

Reference System. The time unit is one day in TDB.

\* \*

\* \*

\* \*

\* \*

\* \* \* \*

\* \*

\* \* \* / 3) The function is a SIMPLIFIED SOLUTION from the planetary theory VSOP2000 (X. Moisson, P. Bretagnon, 2001, Celes. Mechanics & Dyn. Astron., 80, 3/4, 205-213) and is an adaptation of original Fortran code supplied by P. Bretagnon (private comm., 2000).

4) Comparisons over the time span 1900-2100 with this simplified solution and the JPL DE405 ephemeris give the following results:

RMS max Heliocentric: position error 3.7 11.2 velocity error 1.4 5.0 mm/s Barycentric: position error 4.6 13.4 km velocity error 1.4 4.9 mm/s

Comparisons with the JPL DE406 ephemeris show that by 1800 and 2200 the position errors are approximately double their 1900-2100 size. By 1500 and 2500 the deterioration is a factor of 10 and by 1000 and 3000 a factor of 60. The velocity accuracy falls off at about half that rate.

5) It is permissible to use the same array for pvh and pvb, which will receive the barycentric values.

```

```
* *
     iauEra00
* *
* *
* *
    Earth rotation angle (IAU 2000 model).
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
       dj1,dj2
                   double
                              UT1 as a 2-part Julian Date (see note)
* *
* *
    Returned (function value):
* *
                   double
                              Earth rotation angle (radians), range 0-2pi
* *
* *
    Notes:
* *
* *
    1) The UT1 date dj1+dj2 is a Julian Date, apportioned in any
* *
       convenient way between the arguments djl and dj2. For example, JD(UT1)=2450123.7 could be expressed in any of these ways,
* *
* *
       among others:
* *
* *
                 dj1
                                   dj2
* *
* *
             2450123.7
                                    0.0
                                                (JD method)
* *
             2451545.0
                               -1421.3
                                                (J2000 method)
* *
             2400000.5
                               50123.2
                                                (MJD method)
* *
             2450123.5
                                    0.2
                                                (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
        cases where the loss of several decimal digits of resolution
* *
        is acceptable. The J2000 and MJD methods are good compromises
       between resolution and convenience. The date & time method is best matched to the algorithm used: maximum precision is
* *
* *
* *
        delivered when the djl argument is for Ohrs UT1 on the day in
* *
        question and the dj2 argument lies in the range 0 to 1, or vice
* *
        versa.
* *
* *
    2) The algorithm is adapted from Expression 22 of Capitaine et al.
        2000. The time argument has been expressed in days directly,
* *
        and, to retain precision, integer contributions have been
        eliminated. The same formulation is given in IERS Conventions (2003), Chap. 5, Eq. 14.
* *
* *
* *
* *
    Called:
* *
                       normalize angle into range 0 to 2pi

* *
* *
    Fundamental argument, IERS Conventions (2003):
* *
    general accumulated precession in longitude.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
             double
                       TDB, Julian centuries since J2000.0 (Note 1)
* *
* *
   Returned (function value):
* *
                      general precession in longitude, radians (Note 2)
             double
* *
* *
    Notes:
* *
    1) Though t is strictly TDB, it is usually more convenient to use
* *
       TT, which makes no significant difference.
* *
* *
    2) The expression used is as adopted in IERS Conventions (2003).
* *
       is taken from Kinoshita & Souchay (1990) and comes originally
* *
       from Lieske et al. (1977).

                         proper motion in RA (dRA/dt, rad/Jyear)
       drh
                double
* *
       ddh
                double
                          proper motion in Dec (dDec/dt, rad/Jyear)
* *
       pxh
                double
                          parallax (arcsec)
* *
                double
       rvh
                          radial velocity (km/s, positive = receding)
* *
* *
    Notes:
* *
* *
    1) This function transforms FK5 star positions and proper motions
* *
       into the system of the Hipparcos catalog.
* *
* *
    2) The proper motions in RA are dRA/dt rather than
* *
       cos(Dec)*dRA/dt, and are per year rather than per century.
* *
    3) The FK5 to Hipparcos transformation is modeled as a pure
* *
       rotation and spin; zonal errors in the FK5 catalog are not
* *
       taken into account.
* *
* *
    4) See also iauH2fk5, iauFk5hz, iauHfk5z.
* *
* *
    Called:
* *
       iauStarpv
                     star catalog data to space motion pv-vector
* *
       iauFk5hip
                     FK5 to Hipparcos rotation and spin

* *
    iauFk5hip
* *
* *
* *
    FK5 to Hipparcos rotation and spin.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: support function.
* *
* *
    Returned:
* *
      r5h double[3][3] r-matrix: FK5 rotation wrt Hipparcos (Note 2)
* *
       s5h
              double[3]
                           r-vector: FK5 spin wrt Hipparcos (Note 3)
* *
* *
    Notes:
* *
* *
    1) This function models the FK5 to Hipparcos transformation as a
* *
       pure rotation and spin; zonal errors in the FK5 catalogue are
* *
       not taken into account.
* *
* *
    2) The r-matrix r5h operates in the sense:
* *
* *
              P_Hipparcos = r5h x P_FK5
* *
* *
       where P_FK5 is a p-vector in the FK5 frame, and P_Hipparcos is
* *
       the equivalent Hipparcos p-vector.
* *
* *
    3) The r-vector s5h represents the time derivative of the FK5 to
* *
       Hipparcos rotation. The units are radians per year (Julian,
* *
       TDB).
* *
* *
    Called:

\* \*

\* \*

\* \*

\* \*

\* \*

\* \* double FK5 RA (radians), equinox J2000.0, at date r5 FK5 Dec (radians), equinox J2000.0, at date \* \* **d**5 double \* \* date1,date2 double TDB date (Notes 1,2)

\* \* Returned:

double \* \* rh Hipparcos RA (radians) \* \* dh double Hipparcos Dec (radians) \* \*

\* \* Notes:

\* \*

- 1) This function converts a star position from the FK5 system to the Hipparcos system, in such a way that the Hipparcos proper motion is zero. Because such a star has, in general, a non-zero proper motion in the FK5 system, the function requires the date at which the position in the FK5 system was determined.
- 2) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others:

\* \* date2 date1 \* \* \* \* 2450123.7 0.0 (JD method) \* \* -1421.3 2451545.0 (J2000 method) \* \* 2400000.5 50123.2 (MJD method) \* \* 2450123.5 (date & time method)

> The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

- 3) The FK5 to Hipparcos transformation is modeled as a pure rotation and spin; zonal errors in the FK5 catalogue are not taken into account.
- \* \* 4) The position returned by this function is in the Hipparcos \* \* reference system but at date date1+date2. \* \*
  - 5) See also iauFk52h, iauH2fk5, iauHfk5z.

    Returned:
* *
                 double[3][3] rotation matrix
       r
* *
* *
    Notes:
* *
* *
    1) Naming the following points:
* *
* *
              e = J2000.0 ecliptic pole,
* *
             p = GCRS pole,
* *
              E = ecliptic pole of date,
* *
       and
             P = CTP.
* *
* *
       the four Fukushima-Williams angles are as follows:
* *
* *
          gamb = gamma = epE
* *
          phib = phi = pE
* *
          psi = psi = pEP
* *
          eps = epsilon = EP
* *
* *
    2) The matrix representing the combined effects of frame bias,
       precession and nutation is:
* *
* *
          NxPxB = R_1(-eps).R_3(-psi).R_1(phib).R_3(gamb)
* *
* *
    3) Three different matrices can be constructed, depending on the
* *
       supplied angles:
* *
* *
       o To obtain the nutation x precession x frame bias matrix,
* *
          generate the four precession angles, generate the nutation
* *
          components and add them to the psi_bar and epsilon_A angles,
* *
          and call the present function.
* *
* *
       o To obtain the precession x frame bias matrix, generate the
* *
          four precession angles and call the present function.
* *
* *
       o \, To obtain the frame bias matrix, generate the four precession
* *
          angles for date J2000.0 and call the present function.
* *
* *
       The nutation-only and precession-only matrices can if necessary
* *
       be obtained by combining these three appropriately.

```

```
int iauGc2gd ( int n, double xyz[3],
               double *elong, double *phi, double *height )
* *
* *
    iauGc2qd
* *
* *
* *
    Transform geocentric coordinates to geodetic using the specified
* *
    reference ellipsoid.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical transformation.
* *
* *
    Given:
* *
               int
                     ellipsoid identifier (Note 1)
               double[3] geocentric vector (Note 2)
* *
       xyz
* *
* *
    Returned:
* *
      elong
               double
                           longitude (radians, east +ve)
* *
       phi
               double
                           latitude (geodetic, radians, Note 3)
* *
       height double
                           height above ellipsoid (geodetic, Notes 2,3)
* *
* *
    Returned (function value):
* *
                         status: 0 = OK
              int
* *
                                   -1 = illegal identifier (Note 3)
* *
                                    -2 = internal error (Note 3)
* *
* *
   Notes:
* *
    1) The identifier n is a number that specifies the choice of
* *
* *
      reference ellipsoid. The following are supported:
* *
* *
          n
               ellipsoid
* *
* *
                WGS84
          1
* *
                GRS80
          2
* *
                WGS72
* *
       The n value has no significance outside the SOFA software. For
* *
       convenience, symbols WGS84 etc. are defined in sofam.h.
* *
    2) The geocentric vector (xyz, given) and height (height, returned)
* *
       are in meters.
* *
* *
    3) An error status -1 means that the identifier n is illegal. An
* *
       error status -2 is theoretically impossible. In all error cases,
* *
       phi and height are both set to -1e9.
* *
* *
    4) The inverse transformation is performed in the function iauGd2gc.
* *
* *
    Called:
* *
                   Earth reference ellipsoids
       iauEform
* *
       iauGc2gde
                    geocentric to geodetic transformation, general
* *
```

```
int iauGc2gde ( double a, double f, double xyz[3],
                 double *elong, double *phi, double *height )
* *
* *
     iauGc2qde
* *
* *
* *
    Transform geocentric coordinates to geodetic for a reference
* *
    ellipsoid of specified form.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
                double
                            equatorial radius (Notes 2,4)
* *
       f
                double
                            flattening (Note 3)
* *
                double[3] geocentric vector (Note 4)
       xyz
* *
* *
    Returned:
* *
                            longitude (radians, east +ve)
latitude (geodetic, radians)
       elong
                double
* *
       phi
                double
* *
       height double
                           height above ellipsoid (geodetic, Note 4)
* *
* *
    Returned (function value):
* *
                          status: 0 = OK
* *
                                     -1 = illegal f
* *
                                     -2 = illegal a
* *
* *
    Notes:
* *
* *
    1) This function is based on the GCONV2H Fortran subroutine by
* *
       Toshio Fukushima (see reference).
* *
* *
    2) The equatorial radius, a, can be in any units, but meters is
* *
       the conventional choice.
* *
* *
    3) The flattening, f, is (for the Earth) a value around 0.00335,
* *
       i.e. around 1/298.
* *
* *
    4) The equatorial radius, a, and the geocentric vector, xyz,
       must be given in the same units, and determine the units of the returned height, height.
* *
* *
* *
* *
    5) If an error occurs (status < 0), elong, phi and height are
* *
       unchanged.
* *
* *
    6) The inverse transformation is performed in the function
* *
       iauGd2gce.
* *
* *
    7) The transformation for a standard ellipsoid (such as WGS84) can
* *
       more conveniently be performed by calling iauGc2gd, which uses a
* *
       numerical code to identify the required A and F values.
* *

* *
* *
     iauGd2qc
* *
* *
* *
    Transform geodetic coordinates to geocentric using the specified
* *
    reference ellipsoid.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical transformation.
* *
* *
    Given:
* *
                            ellipsoid identifier (Note 1)
                int
* *
       elong
              double
                            longitude (radians, east +ve)
* *
       phi
                double
                            latitude (geodetic, radians, Note 3)
* *
       height double
                            height above ellipsoid (geodetic, Notes 2,3)
* *
* *
    Returned:
* *
                double[3] geocentric vector (Note 2)
* *
* *
    Returned (function value):
* *
                int
                         status: 0 = OK
* *
                                     -1 = illegal identifier (Note 3)
                                     -2 = illegal case (Note 3)
* *
* *
* *
    Notes:
* *
* *
    1) The identifier n is a number that specifies the choice of
* *
       reference ellipsoid. The following are supported:
* *
* *
          n
                ellipsoid
* *
* *
                 WGS84
           1
* *
           2
                 GRS80
* *
                 WGS72
* *
* *
       The n value has no significance outside the SOFA software. For
* *
       convenience, symbols WGS84 etc. are defined in sofam.h.
* *
    2) The height (height, given) and the geocentric vector (xyz,
* *
       returned) are in meters.
* *
* *
    3) No validation is performed on the arguments elong, phi and
* *
       height. An error status -1 means that the identifier n is illegal. An error status -2 protects against cases that would
* *
* *
       lead to arithmetic exceptions. In all error cases, xyz is set
* *
       to zeros.
* *
* *
    4) The inverse transformation is performed in the function iauGc2gd.
* *
* *
    Called:
* *
       iauEform
                     Earth reference ellipsoids
* *
       iauGd2gce
                   geodetic to geocentric transformation, general
* *
                     zero p-vector
* /
```

```

* *
    iauGd2qce
* *
* *
* *
    Transform geodetic coordinates to geocentric for a reference
* *
    ellipsoid of specified form.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
                double
                            equatorial radius (Notes 1,4)
* *
       f
                double
                            flattening (Notes 2,4)
* *
       elong
                double
                            longitude (radians, east +ve)
* *
       phi
                double
                            latitude (geodetic, radians, Note 4)
                           height above ellipsoid (geodetic, Notes 3,4)
* *
       height double
* *
* *
    Returned:
* *
       XVZ
               double[3] geocentric vector (Note 3)
* *
* *
    Returned (function value):
* *
                         status: 0 = OK
* *
                                    -1 = illegal case (Note 4)
* *
    Notes:
* *
* *
    1) The equatorial radius, a, can be in any units, but meters is
* *
       the conventional choice.
* *
* *
    2) The flattening, f, is (for the Earth) a value around 0.00335,
* *
       i.e. around 1/298.
* *
* *
    3) The equatorial radius, {\tt a}, {\tt and} the height, height, must be
* *
       given in the same units, and determine the units of the
* *
       returned geocentric vector, xyz.
* *
    4) No validation is performed on individual arguments. The error
* *
       status -1 protects against (unrealistic) cases that would lead
* *
       to arithmetic exceptions. If an error occurs, xyz is unchanged.
* *
    5) The inverse transformation is performed in the function
* *
       iauGc2qde.
* *
* *
    6) The transformation for a standard ellipsoid (such as WGS84) can
* *
       more conveniently be performed by calling iauGd2gc, which uses a
* *
       numerical code to identify the required a and \ensuremath{\text{f}} values.

* *
     iauGmst00
* *
* *
* *
    Greenwich mean sidereal time (model consistent with IAU 2000
* *
    resolutions).
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
                              UT1 as a 2-part Julian Date (Notes 1,2)
       uta,utb
                   double
* *
       tta, ttb
                   double
                              TT as a 2-part Julian Date (Notes 1,2)
* *
* *
    Returned (function value):
* *
                   double
                              Greenwich mean sidereal time (radians)
* *
* *
    Notes:
* *
* *
    1) The UT1 and TT dates uta+utb and tta+ttb respectively, are both
* *
       Julian Dates, apportioned in any convenient way between the
* *
       argument pairs. For example, JD=2450123.7 could be expressed in
* *
       any of these ways, among others:
* *
* *
               Part A
                               Part B
* *
* *
            2450123.7
                                 0.0
                                             (JD method)
* *
                             -1421.3
            2451545.0
                                             (J2000 method)
* *
            2400000.5
                             50123.2
                                             (MJD method)
* *
            2450123.5
                                 0.2
                                             (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable (in the case of UT; the TT \bar{i}s not at all critical
* *
       in this respect). The J2000 and MJD methods are good compromises
       between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth
* *
* *
* *
       Rotation Angle function, called internally: maximum precision is
* *
       delivered when the uta argument is for Ohrs UT1 on the day in
* *
       question and the utb argument lies in the range 0 to 1, or vice
* *
       versa.
* *
    2) Both UT1 and TT are required, UT1 to predict the Earth rotation
* *
* *
       and TT to predict the effects of precession. If UT1 is used for
* *
       both purposes, errors of order 100 microarcseconds result.
* *
* *
    3) This GMST is compatible with the IAU 2000 resolutions and must be
* *
       used only in conjunction with other IAU 2000 compatible
* *
       components such as precession-nutation and equation of the
* *
       equinoxes.
* *
* *
    4) The result is returned in the range 0 to 2pi.
* *
* *
    5) The algorithm is from Capitaine et al. (2003) and IERS
* *
       Conventions 2003.
* *
* *
    Called:
* *
       iauEra00
                     Earth rotation angle, IAU 2000
* *
       iauAnp
                     normalize angle into range 0 to 2pi
* *

        is acceptable (in the case of UT; the TT \bar{i}s not at all critical
* *
        in this respect). The J2000 and MJD methods are good compromises
       between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth rotation angle function, called internally: maximum precision is
* *
* *
* *
* *
       delivered when the uta argument is for Ohrs UT1 on the day in
* *
       question and the utb argument lies in the range 0 to 1, or vice
* *
        versa.
* *
* *
* *
```

- 2) Both UT1 and TT are required, UT1 to predict the Earth rotation and TT to predict the effects of precession. If UT1 is used for  $\frac{1}{2}$ both purposes, errors of order 100 microarcseconds result.
- 3) This GMST is compatible with the IAU 2006 precession and must not be used with other precession models.
- 4) The result is returned in the range 0 to 2pi.

double iauGmst82(double dj1, double dj2)
* *
     iauGmst82
* *
* *
* *
    Universal Time to Greenwich mean sidereal time (IAU 1982 model).
* *
    This function is part of the International Astronomical Union's
* *
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
       dj1,dj2
                      double
                                  UT1 Julian Date (see note)
* *
* *
    Returned (function value):
* *
                      double
                                 Greenwich mean sidereal time (radians)
* *
* *
    Notes:
* *
* *
    1) The UT1 date dj1+dj2 is a Julian Date, apportioned in any
* *
        convenient way between the arguments djl and dj2. For example, JD(UT1)=2450123.7 could be expressed in any of these ways,
* *
* *
        among others:
* *
* *
                  dj1
                                    dj2
* *
* *
             2450123.7D0
                                    0D0
                                                  (JD method)
* *
                                 -1421.3D0
              2451545D0
                                                  (J2000 method)
* *
             2400000.5D0
                                 50123.2D0
                                                  (MJD method)
* *
             2450123.5D0
                                   0.2D0
                                                  (date & time method)
* *
* *
        The JD method is the most natural and convenient to use in
* *
        cases where the loss of several decimal digits of resolution
* *
        is acceptable. The J2000 and MJD methods are good compromises
        between resolution and convenience. The date & time method is best matched to the algorithm used: maximum accuracy (or, at
* *
* *
* *
        least, minimum noise) is delivered when the djl argument is for
* *
        Ohrs UT1 on the day in question and the dj2 argument lies in the
* *
        range 0 to 1, or vice versa.
* *
    2) The algorithm is based on the IAU 1982 expression. This is always described as giving the GMST at 0 hours UT1. In fact, it
* *
* *
        gives the difference between the GMST and the UT, the steady
* *
        4-minutes-per-day drawing-ahead of ST with respect to UT. When
* *
        whole days are ignored, the expression happens to equal the GMST
* *
        at 0 hours UT1 each day.
* *
     3) In this function, the entire UT1 (the sum of the two arguments
* *
        dj1 and dj2) is used directly as the argument for the standard formula, the constant term of which is adjusted by 12 hours to take account of the noon phasing of Julian Date. The UT1 is then
* *
* *
* *
        added, but omitting whole days to conserve accuracy.
* *
* *
    Called:
* *

               uta
* *
```

uta utb

2450123.7 0.0 (JD method)
2451545.0 -1421.3 (J2000 method)
2400000.5 50123.2 (MJD method)
2450123.5 0.2 (date & time method)

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth Rotation Angle function, called internally: maximum precision is delivered when the uta argument is for Ohrs UTl on the day in question and the utb argument lies in the range 0 to 1, or vice versa.

- 2) The result is compatible with the IAU 2000 resolutions, except that accuracy has been compromised for the sake of speed and convenience in two respects:
  - . UT is used instead of TDB (or TT) to compute the precession component of GMST and the equation of the equinoxes. This results in errors of order 0.1 mas at present.
  - . The IAU 2000B abridged nutation model (McCarthy & Luzum, 2001) is used, introducing errors of up to 1 mas.
- 3) This GAST is compatible with the IAU 2000 resolutions and must be used only in conjunction with other IAU 2000 compatible components such as precession-nutation.
- 4) The result is returned in the range 0 to 2pi.
- 5) The algorithm is from Capitaine et al. (2003) and IERS Conventions 2003.

\* \*

\* \* \* \* uta, utb double UT1 as a 2-part Julian Date (Notes 1,2) TT as a 2-part Julian Date (Notes 1,2) tta.ttb double double[3][3] nutation x precession x bias matrix rnpb

\* \* Returned (function value):

double Greenwich apparent sidereal time (radians)

#### \* \* Notes:

\* \* \* \*

1) The UT1 and TT dates uta+utb and tta+ttb respectively, are both Julian Dates, apportioned in any convenient way between the argument pairs. For example, JD=2450123.7 could be expressed in any of these ways, among others:

		Part B	Part A
ıod)	(JD method	0.0	2450123.7
nethod)	(J2000 met]	-1421.3	2451545.0
(hod)	(MJD method	50123.2	2400000.5
time method)	(date & tim	0.2	2450123.5

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable (in the case of UT; the TT is not at all critical in this respect). The J2000 and MJD methods are good compromises between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth rotation angle function, called internally: maximum precision is delivered when the uta argument is for Ohrs UT1 on the day in question and the utb argument lies in the range 0 to 1, or vice versa.

- 2) Both UT1 and TT are required, UT1 to predict the Earth rotation and TT to predict the effects of precession-nutation. If UT1 is used for both purposes, errors of order 100 microarcseconds result.
- 3) Although the function uses the IAU 2006 series for s+XY/2, it is otherwise independent of the precession-nutation model and can in practice be used with any equinox-based NPB matrix.
- 4) The result is returned in the range 0 to 2pi.

                              50123.2
            2400000.5
                                              (MJD method)
* *
            2450123.5
                                              (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in cases
* *
        where the loss of several decimal digits of resolution is
        acceptable. The J2000 and MJD methods are good compromises
* *
* *
       between resolution and convenience. For UT, the date & time
* *
       method is best matched to the algorithm that is used by the Earth
       Rotation Angle function, called internally: maximum precision is delivered when the uta argument is for Ohrs UT1 on the day in
* *
* *
* *
       question and the utb argument lies in the range 0 to 1, or vice
* *
        versa.
* *
* *
    2) The result is compatible with the IAU 1982 and 1994 resolutions,
       except that accuracy has been compromised for the sake of convenience in that UT is used instead of TDB (or TT) to compute
* *
* *
* *
        the equation of the equinoxes.
* *
    3) This GAST must be used only in conjunction with contemporaneous
* *
        IAU standards such as 1976 precession, 1980 obliquity and 1982
* *
        nutation. It is not compatible with the IAU 2000 resolutions.
* *
* *
    4) The result is returned in the range 0 to 2pi.
* *
* *

* *
* *
    Notes:
* *
* *
    1) This function transforms Hipparcos star positions and proper
* *
       motions into FK5 J2000.0.
* *
* *
    2) The proper motions in RA are dRA/dt rather than
* *
       cos(Dec)*dRA/dt, and are per year rather than per century.
* *
    3) The FK5 to Hipparcos transformation is modeled as a pure
* *
       rotation and spin; zonal errors in the FK5 catalog are not
* *
       taken into account.
* *
* *

                                Dec proper motion (rad/year, Note 4)
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
       convenient way between the two arguments. For example,
* *
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
                            -1421.3
* *
            2451545.0
                                           (J2000 method)
* *
                            50123.2
           2400000.5
                                           (MJD method)
* *
           2450123.5
                                           (date & time method)
                                 0.2
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) The proper motion in RA is dRA/dt rather than cos(Dec)*dRA/dt.
* *
* *
    3) The FK5 to Hipparcos transformation is modeled as a pure rotation
* *
       and spin; zonal errors in the FK5 catalogue are not taken into
* *
       account.
* *
* *
    4) It was the intention that {\tt Hipparcos} should be a close
* *
       approximation to an inertial frame, so that distant objects have
* *
       zero proper motion; such objects have (in general) non-zero
* *
       proper motion in FK5, and this function returns those fictitious
* *
       proper motions.
* *
* *
    5) The position returned by this function is in the FK5 J2000.0
* *
       reference system but at date date1+date2.
* *
* *
    6) See also iauFk52h, iauH2fk5, iauFk5zhz.

        Explanatory Supplement to the Astronomical Almanac,
* *
        P. Kenneth Seidelmann (ed), University Science Books (1992),
* *
        Section 12.92 (p604).
* *
* /
```

```
void iauNum00a(double date1, double date2, double rmatn[3][3])
* *
               iauNum00a
* *
* *
* *
            Form the matrix of nutation for a given date, IAU 2000A model.
* *
             This function is part of the International Astronomical Union's
* *
* *
             SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
            Status: support function.
* *
* *
             Given:
* *
                     date1,date2 double
                                                                                                                    TT as a 2-part Julian Date (Note 1)
* *
* *
             Returned:
* *
                                                                 double[3][3] nutation matrix
                      rmatn
* *
* *
            Notes:
* *
* *
             1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
                       convenient way between the two arguments. For example,
* *
                       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
                      among others:
* *
* *
                                              date1
                                                                                            date2
* *
* *
                                     2450123.7
                                                                                                      0.0
                                                                                                                                       (JD method)
* *
                                     2451545.0
                                                                                         -1421.3
                                                                                                                                        (J2000 method)
* *
                                     2400000.5
                                                                                         50123.2
                                                                                                                                        (MJD method)
* *
                                     2450123.5
                                                                                                      0.2
                                                                                                                                        (date & time method)
* *
* *
                      The JD method is the most natural and convenient to use in
* *
                       cases where the loss of several decimal digits of resolution % \left( \frac{1}{2}\right) =\frac{1}{2}\left( \frac{1}{2}\right) +\frac{1}{2}\left( \frac{1}
* *
                       is acceptable. The J2000 method is best matched to the way
* *
                       the argument is handled internally and will deliver the
* *
                       optimum resolution. The MJD method and the date & time methods
* *
                       are both good compromises between resolution and convenience.
* *
             2) The matrix operates in the sense V(true) = rmatn * V(mean), where
* *
                       the p-vector V(true) is with respect to the true equatorial triad
* *
                       of date and the p-vector V(\mbox{mean}) is with respect to the mean
* *
                       equatorial triad of date.
* *
             3) A faster, but slightly less accurate result (about 1 mas), can be obtained by using instead the iauNum00b function.
* *
* *
* *
* *
             Called:
* *
                       iauPn00a
                                                                 bias/precession/nutation, IAU 2000A
* *

\* \*

\* \* \* / Section 3.222-3 (p114).

```
void iauNum00b(double date1, double date2, double rmatn[3][3])
* *
               iauNum00b
* *
* *
* *
            Form the matrix of nutation for a given date, IAU 2000B model.
* *
             This function is part of the International Astronomical Union's
* *
* *
             SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
            Status: support function.
* *
* *
             Given:
* *
                     date1,date2 double
                                                                                                              TT as a 2-part Julian Date (Note 1)
* *
* *
             Returned:
* *
                                                                double[3][3] nutation matrix
                     rmatn
* *
* *
            Notes:
* *
* *
             1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
                       convenient way between the two arguments. For example,
* *
                      JD(TT)=2450123.7 could be expressed in any of these ways,
* *
                      among others:
* *
* *
                                             date1
                                                                                           date2
* *
* *
                                    2450123.7
                                                                                                    0.0
                                                                                                                                     (JD method)
* *
                                    2451545.0
                                                                                       -1421.3
                                                                                                                                     (J2000 method)
* *
                                    2400000.5
                                                                                       50123.2
                                                                                                                                      (MJD method)
* *
                                    2450123.5
                                                                                                    0.2
                                                                                                                                      (date & time method)
* *
* *
                      The JD method is the most natural and convenient to use in
* *
                       cases where the loss of several decimal digits of resolution % \left( \frac{1}{2}\right) =\frac{1}{2}\left( \frac{1}{2}\right) +\frac{1}{2}\left( \frac{1}
* *
                       is acceptable. The J2000 method is best matched to the way
* *
                       the argument is handled internally and will deliver the
* *
                       optimum resolution. The MJD method and the date & time methods
* *
                      are both good compromises between resolution and convenience.
* *
             2) The matrix operates in the sense V(true) = rmatn * V(mean), where
* *
                       the p-vector V(true) is with respect to the true equatorial triad
* *
                       of date and the p-vector V(\mbox{mean}) is with respect to the mean
* *
                       equatorial triad of date.
* *
* *
             3) The present function is faster, but slightly less accurate (about
* *
                       1 mas), than the iauNum00a function.
* *
* *
             Called:
* *
                      iauPn00b
                                                                bias/precession/nutation, IAU 2000B
* *

                    double[3][3] nutation matrix (Note 3)
       rmatn
* *
* *
    Notes:
* *
* *
* *
    1) The supplied mean obliquity epsa, must be consistent with the
* *
       precession-nutation models from which dpsi and deps were obtained.
* *
* *
    2) The caller is responsible for providing the nutation components;
       they are in longitude and obliquity, in radians and are with
* *
* *
       respect to the equinox and ecliptic of date.
* *
    3) The matrix operates in the sense V(true) = rmatn * V(mean), where the p-vector V(true) is with respect to the true
* *
* *
* *
       equatorial triad of date and the p-vector V(mean) is with
* *
       respect to the mean equatorial triad of date.

date1,date2 double TT as a 2-part Julian Date (Note 1)

Returned:

dpsi,deps double nutation, luni-solar + planetary (Note 2)

#### \*\* Notes:

1) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others:

	date2	date1
method)	0.0	2450123.7
000 method)	-1421.3	2451545.0
D method)	50123.2	2400000.5
te & time method)	0.2	2450123.5

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

2) The nutation components in longitude and obliquity are in radians and with respect to the equinox and ecliptic of date. The obliquity at J2000.0 is assumed to be the Lieske et al. (1977) value of 84381.448 arcsec.

Both the luni-solar and planetary nutations are included. The latter are due to direct planetary nutations and the perturbations of the lunar and terrestrial orbits.

- 3) The function computes the MHB2000 nutation series with the associated corrections for planetary nutations. It is an implementation of the nutation part of the IAU 2000A precession-nutation model, formally adopted by the IAU General Assembly in 2000, namely MHB2000 (Mathews et al. 2002), but with the free core nutation (FCN see Note 4) omitted.
- 4) The full MHB2000 model also contains contributions to the nutations in longitude and obliquity due to the free-excitation of the free-core-nutation during the period 1979-2000. These FCN terms, which are time-dependent and unpredictable, are NOT included in the present function and, if required, must be independently computed. With the FCN corrections included, the present function delivers a pole which is at current epochs accurate to a few hundred microarcseconds. The omission of FCN introduces further errors of about that size.
- \*\* 5) The present function provides classical nutation. The MHB2000
  \*\* algorithm, from which it is adapted, deals also with (i) the
  \*\* offsets between the GCRS and mean poles and (ii) the adjustments
  \*\* in longitude and obliquity due to the changed precession rates.

These additional functions, namely frame bias and precession adjustments, are supported by the SOFA functions iauBi00 and iauPr00.

- 6) The MHB2000 algorithm also provides "total" nutations, comprising the arithmetic sum of the frame bias, precession adjustments, luni-solar nutation and planetary nutation. These total nutations can be used in combination with an existing IAU 1976 precession implementation, such as iauPmat76, to deliver GCRS-to-true predictions of sub-mas accuracy at current dates. However, there are three shortcomings in the MHB2000 model that must be taken into account if more accurate or definitive results are required (see Wallace 2002):
  - (i) The MHB2000 total nutations are simply arithmetic sums, yet in reality the various components are successive Euler rotations. This slight lack of rigor leads to cross terms that exceed 1 mas after a century. The rigorous procedure is to form the GCRS-to-true rotation matrix by applying the bias, precession and nutation in that order.
  - (ii) Although the precession adjustments are stated to be with respect to Lieske et al. (1977), the MHB2000 model does not specify which set of Euler angles are to be used and how the adjustments are to be applied. The most literal and straightforward procedure is to adopt the 4-rotation epsilon\_0, psi\_A, omega\_A, xi\_A option, and to add DPSIPR to psi\_A and DEPSPR to both omega\_A and eps\_A.
  - (iii) The MHB2000 model predates the determination by Chapront et al. (2002) of a 14.6 mas displacement between the J2000.0 mean equinox and the origin of the ICRS frame. It should, however, be noted that neglecting this displacement when calculating star coordinates does not lead to a 14.6 mas change in right ascension, only a small secondorder distortion in the pattern of the precession-nutation effect.

For these reasons, the SOFA functions do not generate the "total nutations" directly, though they can of course easily be generated by calling iauBi00, iauPr00 and the present function and adding the results.

7) The MHB2000 model contains 41 instances where the same frequency appears multiple times, of which 38 are duplicates and three are triplicates. To keep the present code close to the original MHB algorithm, this small inefficiency has not been corrected.

date1,date2 double TT as a 2-part Julian Date (Note 1)

Returned:

dpsi,deps double nutation, luni-solar + planetary (Note 2)

#### \* \* Notes: \* \*

1) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others:

		date2	date1
	(JD method)	0.0	2450123.7
od)	(J2000 method	-1421.3	2451545.0
.)	(MJD method)	50123.2	2400000.5
e method)	(date & time	0.2	2450123.5

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

2) The nutation components in longitude and obliquity are in radians and with respect to the equinox and ecliptic of date. The obliquity at J2000.0 is assumed to be the Lieske et al. (1977) value of 84381.448 arcsec. (The errors that result from using this function with the IAU 2006 value of 84381.406 arcsec can be neglected.)

The nutation model consists only of luni-solar terms, but includes also a fixed offset which compensates for certain long-period planetary terms (Note 7).

- 3) This function is an implementation of the IAU 2000B abridged nutation model formally adopted by the IAU General Assembly in 2000. The function computes the MHB\_2000\_SHORT luni-solar nutation series (Luzum 2001), but without the associated corrections for the precession rate adjustments and the offset between the GCRS and J2000.0 mean poles.
- 4) The full IAU 2000A (MHB2000) nutation model contains nearly 1400 terms. The IAU 2000B model (McCarthy & Luzum 2003) contains only 77 terms, plus additional simplifications, yet still delivers results of 1 mas accuracy at present epochs. This combination of accuracy and size makes the IAU 2000B abridged nutation model  $\,$ suitable for most practical applications.

\* \* The function delivers a pole accurate to 1 mas from 1900 to 2100 \* \* (usually better than 1 mas, very occasionally just outside 1 mas). The full IAU 2000A model, which is implemented in the \* \* \* \* function iauNut00a (q.v.), delivers considerably greater accuracy at current dates; however, to realize this improved accuracy, \* \* corrections for the essentially unpredictable free-core-nutation

(FCN) must also be included.

\* \* \* \*

\* \*

\* \* \* \*

\* \*

\* \*

\* \* \* \* \* \* \* /

- \* \* 5) The present function provides classical nutation. The \* \* MHB\_2000\_SHORT algorithm, from which it is adapted, deals also \* \* with (i) the offsets between the GCRS and mean poles and (ii) the \* \* adjustments in longitude and obliquity due to the changed precession rates. These additional functions, namely frame bias and precession adjustments, are supported by the SOFA functions \* \* \* \* iauBi00 and iauPr00.
  - 6) The MHB\_2000\_SHORT algorithm also provides "total" nutations, comprising the arithmetic sum of the frame bias, precession  $% \left( 1\right) =\left( 1\right) \left( 1\right)$ adjustments, and nutation (luni-solar + planetary). These total nutations can be used in combination with an existing IAU 1976 precession implementation, such as iauPmat76, to deliver GCRSto-true predictions of mas accuracy at current epochs. However, for symmetry with the iauNut00a function (q.v. for the reasons), the SOFA functions do not generate the "total nutations" directly. Should they be required, they could of course easily be generated by calling iauBi00, iauPr00 and the present function and adding the results.
  - 7) The IAU 2000B model includes "planetary bias" terms that are fixed in size but compensate for long-period nutations. The amplitudes quoted in McCarthy & Luzum (2003), namely Dpsi = -1.5835 mas and Depsilon = +1.6339 mas, are optimized for the "total nutations" method described in Note 6. The Luzum (2001) values used in this SOFA implementation, namely -0.135 mas and +0.388 mas, are optimized for the "rigorous" method, where frame bias, precession and nutation are applied separately and in that order. During the interval 1995-2050, the SOFA implementation delivers a maximum error of 1.001 mas (not including FCN).

              date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
                            -1421.3
* *
           2451545.0
                                           (J2000 method)
* *
                            50123.2
           2400000.5
                                           (MJD method)
* *
           2450123.5
                                           (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The nutation components are with respect to the ecliptic of
* *
       date.

```

```
void iauNutm80(double date1, double date2, double rmatn[3][3])
* *
    iauNutm80
* *
* *
* *
   Form the matrix of nutation for a given date, IAU 1980 model.
* *
    This function is part of the International Astronomical Union's
* *
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
      date1,date2
                     double
                                      TDB date (Note 1)
* *
* *
    Returned:
* *
       rmatn
                      double[3][3] nutation matrix
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                             date2
* *
* *
           2450123.7
                                0.0
                                          (JD method)
* *
           2451545.0
                            -1421.3
                                          (J2000 method)
* *
           2400000.5
                            50123.2
                                          (MJD method)
* *
           2450123.5
                                0.2
                                          (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix operates in the sense V(true) = rmatn * V(mean),
* *
       where the p-vector V(true) is with respect to the true
* *
       equatorial triad of date and the p-vector V(mean) is with
       respect to the mean equatorial triad of date.
* *

               psi_J2000
       psi
* *
```

The returned values are all radians.

- \*\* 3) Hilton et al. (2006) Table 1 also contains angles that depend on
  \*\* models distinct from the P03 precession theory itself, namely the

  \*\* IAU 2000A frame bias and nutation. The quoted polynomials are
  \*\* used in other SOFA functions:
  - . iauXy06 contains the polynomial parts of the X and Y series.
  - . iauS06 contains the polynomial part of the s+XY/2 series.
  - . iauPfw06 implements the series for the Fukushima-Williams angles that are with respect to the GCRS pole (i.e. the variants that include frame bias).
  - 4) The IAU resolution stipulated that the choice of parameterization was left to the user, and so an IAU compliant precession implementation can be constructed using various combinations of the angles returned by the present function.
  - 5) The parameterization used by SOFA is the version of the Fukushima-Williams angles that refers directly to the GCRS pole. These angles may be calculated by calling the function iauPfw06. SOFA also supports the direct computation of the CIP GCRS X,Y by series, available by calling iauXy06.
  - 6) The agreement between the different parameterizations is at the 1 microarcsecond level in the present era.
  - 7) When constructing a precession formulation that refers to the GCRS pole rather than the dynamical pole, it may (depending on the choice of angles) be necessary to introduce the frame bias explicitly.
  - 8) It is permissible to re-use the same variable in the returned arguments. The quantities are stored in the stated order.

                     double
                               1st rotation: radians cw around z
* *
       bz.
                     double
                               3rd rotation: radians cw around z
* *
       btheta
                     double
                               2nd rotation: radians ccw around y
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                              date2
* *
* *
            2450123.7
                                 0.0
                                            (JD method)
* *
                             -1421.3
            2451545.0
                                            (J2000 method)
* *
                             50123.2
            2400000.5
                                            (MJD method)
* *
            2450123.5
                                            (date & time method)
                                 0.2
* *
* *
       The JD method is the most natural and convenient to use in
       cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way
* *
* *
* *
       the argument is handled internally and will deliver the
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) The traditional accumulated precession angles zeta_A, z_A,
* *
       theta_A cannot be obtained in the usual way, namely through
* *
       polynomial expressions, because of the frame bias. The latter
* *
       means that two of the angles undergo rapid changes near this
* *
       date. They are instead the results of decomposing the
* *
       precession-bias matrix obtained by using the Fukushima-Williams
       method, which does not suffer from the problem. The
* *
* *
       decomposition returns values which can be used in the
* *
       conventional formulation and which include frame bias.
* *
* *
    3) The three angles are returned in the conventional order, which
* *
       is not the same as the order of the corresponding Euler
* *
       rotations. The precession-bias matrix is
* *
       R_3(-z) \times R_2(+theta) \times R_3(-zeta).
* *
    4) Should zeta_A, z_A, theta_A angles be required that do not
* *
* *
       contain frame bias, they are available by calling the SOFA
* *
       function iauP06e.

                             -1421.3
            2451545.0
                                             (J2000 method)
* *
            2400000.5
                             50123.2
                                             (MJD method)
* *
            2450123.5
                                  0.2
                                             (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
       is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the
* *
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) Naming the following points:
* *
* *
              e = J2000.0 ecliptic pole,
* *
              p = GCRS pole,
* *
              E = mean ecliptic pole of date,
* *
              P = mean pole of date,
       and
* *
* *
       the four Fukushima-Williams angles are as follows:
* *
* *
           gamb = gamma_bar = epE
* *
           phib = phi_bar = pE
* *
          psib = psi_bar = pEP
* *
           epsa = epsilon_A = EP
* *
* *
    3) The matrix representing the combined effects of frame bias and
* *
       precession is:
* *
* *
           PxB = R_1(-epsa).R_3(-psib).R_1(phib).R_3(gamb)
* *
* *
    4) The matrix representing the combined effects of frame bias,
* *
       precession and nutation is simply:
* *
* *
          NxPxB = R_1(-epsa-dE).R_3(-psib-dP).R_1(phib).R_3(gamb)
* *
* *
       where dP and dE are the nutation components with respect to the
* *
       ecliptic of date.

int iauPlan94(double date1, double date2, int np, double pv[2][3])
* *
     iauPlan94
* *
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Approximate heliocentric position and velocity of a nominated major
* *
    planet: Mercury, Venus, EMB, Mars, Jupiter, Saturn, Uranus or
* *
    Neptune (but not the Earth itself).
* *
* *
    Given:
* *
       date1 double
                             TDB date part A (Note 1)
                             TDB date part B (Note 1)
* *
       date2 double
* *
                             planet (1=Mercury, 2=Venus, 3=EMB, 4=Mars,
       np
               int
* *
                                 5=Jupiter, 6=Saturn, 7=Uranus, 8=Neptune)
* *
* *
    Returned (argument):
* *
               double[2][3] planet p,v (heliocentric, J2000.0, AU,AU/d)
* *
* *
    Returned (function value):
* *
                             status: -1 = illegal NP (outside 1-8)
* *
                                       0 = OK
* *
                                      +1 = warning: year outside 1000-3000
+2 = warning: failed to converge
* *
* *
* *
    Notes:
* *
* *
    1) The date date1+date2 is in the TDB time scale (in practice TT can
* *
       be used) and is a Julian Date, apportioned in any convenient way
* *
       between the two arguments. For example, JD(TDB)=2450123.7 could
* *
       be expressed in any of these ways, among others:
* *
* *
               date1
                               date2
* *
* *
            2450123.7
                                 0.0
                                             (JD method)
* *
                             -1421.3
            2451545.0
                                             (J2000 method)
* *
```

2400000.5 50123.2 (MJD method) 2450123.5 0.2 (date & time method)

\* \*

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. The limited accuracy of the present algorithm is such that any of the methods is satisfactory.

- 2) If an np value outside the range 1-8 is supplied, an error status (function value -1) is returned and the pv vector set to zeroes.
- 3) For np=3 the result is for the Earth-Moon Barycenter. To obtain the heliocentric position and velocity of the Earth, use instead the SOFA function iauEpv00.
- 4) On successful return, the array pv contains the following:

```
pv[0][0]
           Х
pv[0][1]
                     heliocentric position, AU
           У
pv[0][2]
pv[1][0]
           xdot
pv[1][1]
           ydot
                     heliocentric velocity, AU/d
           zdot
pv[1][2]
```

The reference frame is equatorial and is with respect to the

mean equator and equinox of epoch J2000.0.

\* \*

\* \*

5) The algorithm is due to J.L. Simon, P. Bretagnon, J. Chapront, M. Chapront-Touze, G. Francou and J. Laskar (Bureau des Longitudes, Paris, France). From comparisons with JPL ephemeris DE102, they quote the following maximum errors over the interval 1800-2050:

	L (arcsec)	B (arcsec)	R (km)
Mercury	4	1	300
Venus	5	1	800
EMB	6	1	1000
Mars	17	1	7700
Jupiter	71	5	76000
Saturn	81	13	267000
Uranus	86	7	712000
Neptune	11	1	253000

Over the interval 1000-3000, they report that the accuracy is no worse than 1.5 times that over 1800-2050. Outside 1000-3000 the accuracy declines.

Comparisons of the present function with the JPL DE200 ephemeris give the following RMS errors over the interval 1960-2025:

	position (km)	velocity (m/s)
Mercury	334	0.437
Venus	1060	0.855
EMB	2010	0.815
Mars	7690	1.98
Jupiter	71700	7.70
Saturn	199000	19.4
Uranus	564000	16.4
Neptune	158000	14.4

Comparisons against DE200 over the interval 1800-2100 gave the following maximum absolute differences. (The results using DE406 were essentially the same.)

	L (arcsec)	B (arcsec)	R (km)	Rdot (m/s)
Mercury	7	1	500	0.7
Venus	7	1	1100	0.9
EMB	9	1	1300	1.0
Mars	26	1	9000	2.5
Jupiter	78	6	82000	8.2
Saturn	87	14	263000	24.6
Uranus	86	7	661000	27.4
Neptune	11	2	248000	21.4

- 6) The present SOFA re-implementation of the original Simon et al. Fortran code differs from the original in the following respects:
  - \* C instead of Fortran.
  - \* The date is supplied in two parts.
  - \* The result is returned only in equatorial Cartesian form; the ecliptic longitude, latitude and radius vector are not returned.
  - $^{\star}$  The result is in the J2000.0 equatorial frame, not ecliptic.
  - \* More is done in-line: there are fewer calls to subroutines.
  - \* Different error/warning status values are used.
  - \* A different Kepler's-equation-solver is used (avoiding use of double precision complex).
  - \* Polynomials in t are nested to minimize rounding errors.

\* \* Explicit double constants are used to avoid mixed-mode \* \* expressions. \* \* \* \* None of the above changes affects the result significantly. \* \* \* \* 7) The returned status indicates the most serious condition \* \* encountered during execution of the function. Illegal np is \* \* considered the most serious, overriding failure to converge, \* \* which in turn takes precedence over the remote date warning. \* \* \* \* Called: \* \* iauAnp normalize angle into range 0 to 2pi \* \* \* \* Reference: Simon, J.L, Bretagnon, P., Chapront, J., Chapront-Touze, M., Francou, G., and Laskar, J., Astron. Astrophys. 282, 663 (1994). \* \* \* \*

* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix operates in the sense V(date) = RMATP * V(J2000),
* *
       where the p-vector V(J2000) is with respect to the mean
* *
       equatorial triad of epoch J2000.0 and the p-vector V(date)
* *
       is with respect to the mean equatorial triad of the given
* *
* *
* *
    3) Though the matrix method itself is rigorous, the precession
* *
       angles are expressed through canonical polynomials which are
* *
       valid only for a limited time span. In addition, the IAU 1976
* *
       precession rate is known to be imperfect. The absolute accuracy
* *
       of the present formulation is better than 0.1 arcsec from
       1960AD to 2040AD, better than 1 arcsec from 1640AD to 2360AD,
* *
       and remains below 3 arcsec for the whole of the period 500BC to 3000AD. The errors exceed 10 arcsec outside the
* *
* *
* *
       range 1200BC to 3900AD, exceed 100 arcsec outside 4200BC to
* *
       5600AD and exceed 1000 arcsec outside 6800BC to 8200AD.
* *

    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       date1,date2 double
                                        TT as a 2-part Julian Date (Note 1)
* *
       dpsi,deps
                      double
                                        nutation (Note 2)
* *
* *
    Returned:
* *
       epsa
                      double
                                        mean obliquity (Note 3)
* *
                      double[3][3]
                                       frame bias matrix (Note 4)
       rh
* *
       rp
                      double[3][3]
                                        precession matrix (Note 5)
* *
                      double[3][3]
                                        bias-precession matrix (Note 6)
       rbp
* *
                      double[3][3]
                                        nutation matrix (Note 7)
       rn
* *
       rbpn
                      double[3][3]
                                        GCRS-to-true matrix (Note 8)
* *
* *
    Notes:
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example,
* *
* *
* *
        JD(TT)=2450123.7 could be expressed in any of these ways,
* *
        among others:
* *
* *
```

* *	date1	date2	
* *			
* *	2450123.7	0.0	(JD method)
* *	2451545.0	-1421.3	(J2000 method)
* *	2400000.5	50123.2	(MJD method)
* *	2450123.5	0.2	(date & time method)

\* \* \* \*

\* \*

\* \* \* \*

\* \*

\* \* \* \*

\* \*

\* \*

\* \*

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

- 2) The caller is responsible for providing the nutation components; they are in longitude and obliquity, in radians and are with respect to the equinox and ecliptic of date. For high-accuracy applications, free core nutation should be included as well as any other relevant corrections to the position of the CIP.
- The returned mean obliquity is consistent with the IAU 2006 precession.
- 4) The matrix rb transforms vectors from GCRS to J2000.0 mean equator and equinox by applying frame bias.
- 5) The matrix rp transforms vectors from J2000.0 mean equator and equinox to mean equator and equinox of date by applying precession.
- \*\* 6) The matrix rbp transforms vectors from GCRS to mean equator and equinox of date by applying frame bias then precession. It is the product rp x rb.

- \*\* 7) The matrix rn transforms vectors from mean equator and equinox
  \*\* of date to true equator and equinox of date by applying the
  \*\* nutation (luni-solar + planetary).
  \*\*
- \*\* 8) The matrix rbpn transforms vectors from GCRS to true equator and
  \*\* equinox of date. It is the product rn x rbp, applying frame
  \*\* bias, precession and nutation in that order.
  \*\*
- \*\* 9) The X,Y,Z coordinates of the IAU 2000B Celestial Intermediate 
  \*\* Pole are elements (3,1-3) of the matrix rbpn.
- \*\* 10) It is permissible to re-use the same array in the returned 
  \*\* arguments. The arrays are filled in the stated order.

    Form the matrix of precession/nutation for a given date, IAU 1976
* *
    precession model, IAU 1980 nutation model.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       date1,date2
                       double
                                        TDB date (Note 1)
* *
* *
    Returned:
* *
                       double[3][3] combined precession/nutation matrix
       rmatpn
* *
* *
    Notes:
* *
* *
    1) The TDB date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TDB)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                               date2
* *
* *
            2450123.7
                                            (JD method)
                                 0.0
                             -1421.3
* *
            2451545.0
                                            (J2000 method)
* *
                             50123.2
            2400000.5
                                            (MJD method)
* *
                                            (date & time method)
            2450123.5
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The matrix operates in the sense V(date) = rmatpn * V(J2000),
* *
       where the p-vector V(date) is with respect to the true equatorial
       triad of date date1+date2 and the p-vector V(J2000) is with
* *
       respect to the mean equatorial triad of epoch J2000.0.
* *
* *
    Called:

* *
     iau P o m 0 0
* *
* *
* *
    Form the matrix of polar motion for a given date, IAU 2000.
* *
    This function is part of the International Astronomical Union's
* *
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       xp,yp
                 double
                             coordinates of the pole (radians, Note 1)
* *
                  double
                            the TIO locator s' (radians, Note 2)
       sp
* *
* *
    Returned:
* *
                 double[3][3] polar-motion matrix (Note 3)
       rpom
* *
* *
    Notes:
* *
* *
    1) The arguments xp and yp are the coordinates (in radians) of the
* *
        Celestial Intermediate Pole with respect to the International
* *
        Terrestrial Reference System (see IERS Conventions 2003),
* *
       measured along the meridians to 0 and 90 deg west respectively.
* *
* *
    2) The argument sp is the TIO locator \mathbf{s}^{\,\prime}\,, in radians, which
* *
        positions the Terrestrial Intermediate Origin on the equator. It
* *
        is obtained from polar motion observations by numerical
        integration, and so is in essence unpredictable. However, it is
* *
* *
        dominated by a secular drift of about 47 microarcseconds per
       century, and so can be taken into account by using s' = -47*t, where t is centuries since J2000.0. The function iauSp00
* *
* *
* *
        implements this approximation.
* *
    3) The matrix operates in the sense V(TRS) = rpom * V(CIP), meaning
* *
* *
        that it is the final rotation when computing the pointing
* *
        direction to a celestial source.
* *
* *
    Called:

date1,date2 double TT as a 2-part Julian Date (Note 1)

Returned:

dpsipr, depspr double precession corrections (Notes 2,3)

### \*\* Notes:

1) The TT date date1+date2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others:

	date2	date1
(JD method)	0.0	2450123.7
(J2000 method)	-1421.3	2451545.0
(MJD method)	50123.2	2400000.5
(date & time method)	0.2	2450123.5

The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

- 2) The precession adjustments are expressed as "nutation components", corrections in longitude and obliquity with respect to the J2000.0 equinox and ecliptic.
- 3) Although the precession adjustments are stated to be with respect to Lieske et al. (1977), the MHB2000 model does not specify which set of Euler angles are to be used and how the adjustments are to be applied. The most literal and straightforward procedure is to adopt the 4-rotation epsilon\_0, psi\_A, omega\_A, xi\_A option, and to add dpsipr to psi\_A and depspr to both omega\_A and eps\_A.
- 4) This is an implementation of one aspect of the IAU 2000A nutation model, formally adopted by the IAU General Assembly in 2000, namely MHB2000 (Mathews et al. 2002).

       theta
                    double
* *
* *
    Notes:
* *
* *
    1) The epochs ep01+ep02 and ep11+ep12 are Julian Dates, apportioned
* *
       in any convenient way between the arguments epn1 and epn2. For
* *
       example, JD(TDB)=2450123.7 could be expressed in any of these
* *
       ways, among others:
* *
* *
                epn1
                               epn2
* *
* *
           2450123.7
                                 0.0
                                            (JD method)
* *
           2451545.0
                             -1421.3
                                            (J2000 method)
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
           2450123.5
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in cases
* *
       where the loss of several decimal digits of resolution is
       acceptable. The J2000 method is best matched to the way the
* *
       argument is handled internally and will deliver the optimum
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
       The two epochs may be expressed using different methods, but at
* *
       the risk of losing some resolution.
* *
* *
    2) The accumulated precession angles zeta, z, theta are expressed
* *
       through canonical polynomials which are valid only for a limited
* *
       time span. In addition, the IAU 1976 precession rate is known to
* *
       be imperfect. The absolute accuracy of the present formulation
* *
       is better than 0.1 arcsec from 1960AD to 2040AD, better than
       1 arcsec from 1640AD to 2360AD, and remains below 3 arcsec for
* *
* *
       the whole of the period 500BC to 3000AD. The errors exceed
* *
       10 arcsec outside the range 1200BC to 3900AD, exceed 100 arcsec
* *
       outside 4200BC to 5600AD and exceed 1000 arcsec outside 6800BC to
* *
       8200AD.
* *
* *
    3) The three angles are returned in the conventional order, which
* *
       is not the same as the order of the corresponding Euler
* *
       rotations. The precession matrix is
* *
       R_3(-z) \times R_2(+theta) \times R_3(-zeta).

       rd
                 double
                                 rate of change of r
* *
* *
    Notes:
* *
* *
    1) If the position part of pv is null, theta, phi, td and pd
* *
       are indeterminate. This is handled by extrapolating the
* *
       position through unit time by using the velocity part of
* *
       pv. This moves the origin without changing the direction
* *
       of the velocity component. If the position and velocity
       components of pv are both null, zeroes are returned for all
* *
* *
        six results.
* *
    2) If the position is a pole, theta, td and pd are indeterminate. In such cases zeroes are returned for all three.
* *
* *
* *
```

                                  radial velocity (km/s, positive = receding)
* *
* *
    Returned (function value):
* *
                int
                                   status:
* *
                                      0 = OK
* *
                                     -1 = superluminal speed (Note 5)
* *
                                     -2 = null position vector
* *
* *
    Notes:
* *
* *
    1) The specified pv-vector is the coordinate direction (and its rate
* *
        of change) for the date at which the light leaving the star
* *
        reached the solar-system barycenter.
* *
* *
     2) The star data returned by this function are "observables" for an
* *
        imaginary observer at the solar-system barycenter. Proper motion
* *
        and radial velocity are, strictly, in terms of barycentric
* *
        coordinate time, TCB. For most practical applications, it is
* *
        permissible to neglect the distinction between TCB and ordinary
        "proper" time on Earth (TT/TAI). The result will, as a rule, be limited by the intrinsic accuracy of the proper-motion and radial-velocity data; moreover, the supplied pv-vector is likely
* *
* *
        to be merely an intermediate result (for example generated by the function iauStarpv), so that a change of time unit will cancel
* *
* *
* *
        out overall.
* *
* *
        In accordance with normal star-catalog conventions, the object's
* *
        right ascension and declination are freed from the effects of
        secular aberration. The frame, which is aligned to the catalog equator and equinox, is Lorentzian and centered on the SSB.
* *
* *
* *
* *
```

Summarizing, the specified pv-vector is for most stars almost identical to the result of applying the standard geometrical "space motion" transformation to the catalog data. The differences, which are the subject of the Stumpff paper cited

below, are:

\* \* \* \*

\* \*

\* \*

\* \* \* \*

\* \*

\* \*

\* \*

\* \* \* \*

\* \*

- (i) In stars with significant radial velocity and proper motion, the constantly changing light-time distorts the apparent proper motion. Note that this is a classical, not a relativistic, effect.
- (ii) The transformation complies with special relativity.
- \*\* 3) Care is needed with units. The star coordinates are in radians
  \*\* and the proper motions in radians per Julian year, but the
  parallax is in arcseconds; the radial velocity is in km/s, but
  the pv-vector result is in AU and AU/day.

4) The proper motions are the rate of change of the right ascension \* \* and declination at the catalog epoch and are in radians per Julian \* \* year. The RA proper motion is in terms of coordinate angle, not true angle, and will thus be numerically larger at high \* \* \* \* declinations. \* \* \* \* 5) Straight-line motion at constant speed in the inertial frame is \* \* assumed. If the speed is greater than or equal to the speed of \* \* light, the function aborts with an error status. \* \* \* \* 6) The inverse transformation is performed by the function iauStarpv. \* \* \* \* Called: \* \* decompose p-vector into modulus and direction iauPn \* \* iauPdp scalar product of two p-vectors \* \* multiply p-vector by scalar iauSxp \* \* iauPmp p-vector minus p-vector \* \* modulus of p-vector p-vector plus p-vector iauPm \* \* iauPpp \* \* pv-vector to spherical iauPv2s \* \* iauAnp normalize angle into range 0 to 2pi

       arguments.
* *
* /
```

```
void iauRm2v(double r[3][3], double w[3])
* *
    iauRm2v
* *
* *
* *
    Express an r-matrix as an r-vector.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                 double[3][3] rotation matrix
      r
* *
* *
    Returned:
* *
                 double[3] rotation vector (Note 1)
* *
* *
    Notes:
**
* *
    1) A rotation matrix describes a rotation through some angle about
* *
       some arbitrary axis called the Euler axis. The "rotation vector"
* *
       returned by this function has the same direction as the Euler axis,
* *
       and its magnitude is the angle in radians. (The magnitude and
* *
       direction can be separated by means of the function iauPn.)
* *
* *
    2) If r is null, so is the result. If r is not a rotation matrix the result is undefined; r must be proper (i.e. have a positive
* *
* *
       determinant) and real orthogonal (inverse = transpose).
* *
* *
    3) The reference frame rotates clockwise as seen looking along
* *
       the rotation vector from the origin.
```

\* \* \* /

```
void iauRv2m(double w[3], double r[3][3])
* *
    iauRv2m
* *
* *
* *
   Form the r-matrix corresponding to a given r-vector.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                 double[3]
                                 rotation vector (Note 1)
      W
* *
* *
    Returned:
* *
                 double[3][3] rotation matrix
      r
* *
* *
    Notes:
* *
* *
    1) A rotation matrix describes a rotation through some angle about
* *
       some arbitrary axis called the Euler axis. The "rotation vector"
* *
       supplied to This function has the same direction as the Euler
* *
       axis, and its magnitude is the angle in radians.
* *
* *
    2) If w is null, the unit matrix is returned.
* *
* *
    3) The reference frame rotates clockwise as seen looking along the
* *
       rotation vector from the origin.
* *
```

```
void iauRx(double phi, double r[3][3])
* *
     iauRx
* *
* *
**
    Rotate an r-matrix about the x-axis.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
       phi
                 double
                                     angle (radians)
* *
* *
    Given and returned:
* *
                 double[3][3]
                                     r-matrix, rotated
       r
* *
* *
    Notes:
* *
    1) Calling this function with positive phi incorporates in the
* *
* *
        supplied r-matrix r an additional rotation, about the x-axis, anticlockwise as seen looking towards the origin from positive x.
* *
* *
* *
     2) The additional rotation can be represented by this matrix:
* *
* *
                 1
                             0
* *
* *
                  0
                       + cos(phi)
                                      + sin(phi)
* *
* *
                 0
                      - sin(phi)
                                     + cos(phi)
* *
```

    Given and returned:
* *
      r double[3][3] r-matrix, rotated
* *
* *
    Notes:
* *
* *
    1) Calling this function with positive theta incorporates in the
* *
       supplied r-matrix r an additional rotation, about the y-axis,
* *
       anticlockwise as seen looking towards the origin from positive y.
* *
* *
    2) The additional rotation can be represented by this matrix:
* *
               + cos(theta)
* *
                                          - sin(theta)
                                  0
* *
* *
* *
* *
              + sin(theta)
                                 0
                                         + cos(theta)
* *
```

```
void iauRz(double psi, double r[3][3])
* *
     iauRz
* *
* *
** Rotate an r-matrix about the z-axis.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
       psi
                double
                                    angle (radians)
* *
* *
    Given and returned:
* *
                double[3][3] r-matrix, rotated
       r
* *
* *
    Notes:
* *
* *
    1) Calling this function with positive psi incorporates in the
* *
        supplied r-matrix r an additional rotation, about the z-axis, anticlockwise as seen looking towards the origin from positive z.
* *
* *
* *
     2) The additional rotation can be represented by this matrix:
* *
* *
                + cos(psi) + sin(psi)
                                                   0
* *
* *
                 -\sin(psi) + \cos(psi)
* *
* *
                                     0
                      0
                                                    1 )
* *
```

```
double iauS00(double date1, double date2, double x, double y)
* *
     iaus 0 0
* *
* *
* *
    The CIO locator s, positioning the Celestial Intermediate Origin on
* *
    the equator of the Celestial Intermediate Pole, given the CIP's X,Y
* *
    coordinates. Compatible with IAU 2000A precession-nutation.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
       date1,date2
                      double
                                TT as a 2-part Julian Date (Note 1)
* *
                      double
                                CIP coordinates (Note 3)
       X, Y
* *
* *
    Returned (function value):
* *
                      double
                                the CIO locator s in radians (Note 2)
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                0.0
                                           (JD method)
* *
           2451545.0
                            -1421.3
                                           (J2000 method)
* *
           2400000.5
                            50123.2
                                           (MJD method)
* *
           2450123.5
                                 0.2
                                           (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
* *
       the argument is handled internally and will deliver the
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The CIO locator s is the difference between the right ascensions
* *
       of the same point in two systems: the two systems are the GCRS
* *
       and the CIP, CIO, and the point is the ascending node of the
* *
       CIP equator. The quantity s remains below 0.1\ \mathrm{arcsecond}
* *
       throughout 1900-2100.
* *
    3) The series used to compute s is in fact for s+XY/2, where X and Y
* *
       are the x and y components of the CIP unit vector; this series
* *
       is more compact than a direct series for s would be.
* *
       function requires X,Y to be supplied by the caller, who is
* *
       responsible for providing values that are consistent with the
* *
       supplied date.
* *
* *
    4) The model is consistent with the IAU 2000A precession-nutation.
* *
* *
    Called:

```
void iauS2c(double theta, double phi, double c[3])
* *
    iauS2c
* *
**
\ensuremath{^{**}} Convert spherical coordinates to Cartesian.
* *
** This function is part of the International Astronomical Union's
** SOFA (Standards Of Fundamental Astronomy) software collection.
* *
**
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                                   longitude angle (radians)
latitude angle (radians)
       theta
                    double
* *
       phi
                    double
* *
** Returned:
* *
                   double[3] direction cosines
        C
* *
* /
```

```
void iauS2p(double theta, double phi, double r, double p[3])
* *
    iauS2p
* *
* *
* *
   Convert spherical polar coordinates to p-vector.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
       theta
                 double
                               longitude angle (radians)
* *
                 double
       phi
                               latitude angle (radians)
* *
                 double
                               radial distance
* *
* *
   Returned:
* *
       р
                 double[3] Cartesian coordinates
* *
* *
    Called:
* *
        iauS2c
                      spherical coordinates to unit vector
* *
        iauSxp
                     multiply p-vector by scalar
* *
* /
```

```
void iauS2pv(double theta, double phi, double r,
              double td, double pd, double rd, double pv[2][3])
**
* *
    iauS2pv
* *
* *
* *
    Convert position/velocity from spherical to Cartesian coordinates.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                                  longitude angle (radians)
       theta
                double
* *
       phi
                                  latitude angle (radians)
                double
* *
                 double
                                 radial distance
       r
                                  rate of change of theta rate of change of phi
* *
       td
                double
* *
       pd
                double
* *
       rd
                                 rate of change of r
                double
* *
* *
   Returned:
* *
                double[2][3] pv-vector
       pv
* *
* /
```

```
void iauS2xpv(double s1, double s2, double pv[2][3], double spv[2][3])
* *
    iauS2xpv
* *
* *
** Multiply a pv-vector by two scalars.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
               double
                                scalar to multiply position component by
      s1
* *
       s2
               double scalar to multiply velocity component by double[2][3] pv-vector
* *
       pv
* *
* *
   Returned:
* *
               double[2][3] pv-vector: p scaled by s1, v scaled by s2
       spv
* *
* *
    Note:
* *
       It is permissible for pv and spv to be the same array.
**
* *
    Called:
* *
                     multiply p-vector by scalar
       iauSxp
* *
* /
```

```
double iauSepp(double a[3], double b[3])
* *
    iauSepp
* *
* *
* *
    Angular separation between two p-vectors.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
    Given:
* *
                                first p-vector (not necessarily unit length)
                double[3]
       а
* *
                                second p-vector (not necessarily unit length)
                double[3]
* *
* *
    Returned (function value):
* *
                                angular separation (radians, always positive)
                double
* *
* *
    Notes:
* *
    1) If either vector is null, a zero result is returned.
* *
* *
    2) The angular separation is most simply formulated in terms of
* *
        scalar product. However, this gives poor accuracy for angles near zero and pi. The present algorithm uses both cross product
* *
* *
        and dot product, to deliver full accuracy whatever the size of
* *
        the angle.
* *
* *
    Called:
* *
                       vector product of two p-vectors
        iauPxp
* *
        iauPm
                     modulus of p-vector
* *
        iauPdp
                      scalar product of two p-vectors
```

```
double iauSeps(double al, double ap, double bl, double bp)
* *
    iauSeps
* *
* *
**
    Angular separation between two sets of spherical coordinates.
* *
    This function is part of the International Astronomical Union's SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
* *
    Status: vector/matrix support function.
* *
* *
* *
    Given:
* *
               double
                             first longitude (radians)
      al
* *
               double
                            first latitude (radians)
       ap
* *
       bl
               double
                             second longitude (radians)
* *
      bp
                             second latitude (radians)
               double
* *
* *
    Returned (function value):
* *
               double
                          angular separation (radians)
* *
* *
   Called:
* *
       iauS2c
                     spherical coordinates to unit vector
* *
                      angular separation between two p-vectors
       iauSepp
* *
* /
```

```
double iauSp00(double date1, double date2)
* *
    iauSp00
* *
* *
    The TIO locator s^\prime, positioning the Terrestrial Intermediate Origin on the equator of the Celestial Intermediate Pole.
* *
* *
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
       date1,date2 double
                                TT as a 2-part Julian Date (Note 1)
* *
* *
    Returned (function value):
* *
                                the TIO locator s' in radians (Note 2)
                     double
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
               date1
                               date2
* *
* *
            2450123.7
                                            (JD method)
                                 0.0
                             -1421.3
* *
            2451545.0
                                            (J2000 method)
* *
                             50123.2
            2400000.5
                                            (MJD method)
* *
                                             (date & time method)
            2450123.5
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) The TIO locator s' is obtained from polar motion observations by
       numerical integration, and so is in essence unpredictable.
* *
       However, it is dominated by a secular drift of about
* *
       47 microarcseconds per century, which is the approximation
* *
       evaluated by the present function.
* *

                              -1421.3
            2451545.0
                                              (J2000 method)
* *
            2400000.5
                                              (MJD method)
                              50123.2
* *
            2450123.5
                                  0.2
                                              (date & time method)
* *
* *
        The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
        is acceptable. The J2000 method is best matched to the way
* *
```

the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience.

\* \*

\* \*

\* \* \* \*

\* \*

\* \*

2) In accordance with normal star-catalog conventions, the object's  $\label{eq:right} \mbox{right ascension and declination are freed from the effects of}$ secular aberration. The frame, which is aligned to the catalog equator and equinox, is Lorentzian and centered on the SSB.

The proper motions are the rate of change of the right ascension and declination at the catalog epoch and are in radians per TDB Julian year.

The parallax and radial velocity are in the same frame.

- 3) Care is needed with units. The star coordinates are in radians and the proper motions in radians per Julian year, but the parallax is in arcseconds.
- 4) The RA proper motion is in terms of coordinate angle, not true angle. If the catalog uses arcseconds for both RA and Dec proper motions, the RA proper motion will need to be divided by cos(Dec) before use.
- \* \* 5) Straight-line motion at constant speed, in the inertial frame, \* \* is assumed.
  - 6) An extremely small (or zero or negative) parallax is interpreted to mean that the object is on the "celestial sphere", the radius of which is an arbitrary (large) value (see the iauStarpv function for the value used). When the distance is overridden in this way, the status, initially zero, has 1 added to it.
- 7) If the space velocity is a significant fraction of c (see the \* \* constant VMAX in the function iauStarpv), it is arbitrarily set to zero. When this action occurs, 2 is added to the status. \* \*
- \* \* 8) The relativistic adjustment carried out in the iauStarpv function  $\ensuremath{\text{S}}$ \* \* involves an iterative calculation. If the process fails to \* \* converge within a set number of iterations, 4 is added to the \* \* status. \* \*

                                                                                    status:
* *
                                                                                                 0 = no warnings
* *
                                                                                                 1 = distance overridden (Note 6)
* *
                                                                                                 2 = excessive speed (Note 7)
* *
                                                                                                 4 = solution didn't converge (Note 8)
* *
                                                                                        else = binary logical OR of the above
* *
* *
            Notes:
* *
* *
            1) The star data accepted by this function are "observables" for an
* *
                     imaginary observer at the solar-system barycenter. Proper motion
* *
                     and radial velocity are, strictly, in terms of barycentric
                    coordinate time, TCB. For most practical applications, it is permissible to neglect the distinction between TCB and ordinary
* *
* *
                     "proper" time on Earth (TT/TAI). The result will, as a rule, be
                     limited by the intrinsic accuracy of the proper-motion and radial-velocity data; moreover, the pv-vector is likely to be
* *
* *
                     merely an intermediate result, so that a change of time unit
* *
                    would cancel out overall.
* *
* *
                     In accordance with normal star-catalog conventions, the object's
* *
                     right ascension and declination are freed from the effects of
* *
                     secular aberration. The frame, which is aligned to the catalog equator and equinox, is Lorentzian and centered on the SSB.
* *
* *
* *
            2) The resulting position and velocity pv-vector is with respect to
* *
                     the same frame and, like the catalog coordinates, is freed from
* *
                     the effects of secular aberration. Should the "coordinate
* *
                     direction", where the object was located at the catalog epoch, be
* *
                     required, it may be obtained by calculating the magnitude of the
* *
                     position vector pv[0][0-2] dividing by the speed of light in AU/day to give the light-time, and then multiplying the space
* *
* *
                     velocity pv[1][0-2] by this light-time and adding the result to
* *
                     pv[0][0-2].
* *
* *
                     Summarizing, the pv-vector returned is for most stars almost
* *
                     identical to the result of applying the standard geometrical "space motion" transformation. The differences, which are the
* *
* *
                     subject of the Stumpff paper referenced below, are:
* *
* *
                     (i) In stars with significant radial velocity and proper motion,
* *
                     the constantly changing light-time distorts the apparent proper % \left( 1\right) =\left( 1\right) \left( 
* *
                     motion. Note that this is a classical, not a relativistic,
                     effect.
```

(ii) The transformation complies with special relativity.

3) Care is needed with units. The star coordinates are in radians and the proper motions in radians per Julian year, but the parallax is in arcseconds; the radial velocity is in km/s, but the pv-vector result is in AU and AU/day.

\* \* \* \* \* \*

\* \*

\*\*

\* \*

\* \*

4) The RA proper motion is in terms of coordinate angle, not true angle. If the catalog uses arcseconds for both RA and Dec proper motions, the RA proper motion will need to be divided by cos(Dec) before use.

\* \* \* \*

\*\* 5) Straight-line motion at constant speed, in the inertial frame,
\*\* is assumed.

\* \* \* \*

6) An extremely small (or zero or negative) parallax is interpreted to mean that the object is on the "celestial sphere", the radius of which is an arbitrary (large) value (see the constant PXMIN). When the distance is overridden in this way, the status, initially zero, has 1 added to it.

7) If the space velocity is a significant fraction of c (see the constant VMAX), it is arbitrarily set to zero. When this action occurs, 2 is added to the status.

\* \* \* \* \* \*

\* \*

8) The relativistic adjustment involves an iterative calculation. If the process fails to converge within a set number (IMAX) of iterations, 4 is added to the status.

\* \* \* \*

9) The inverse transformation is performed by the function iauPvstar.

```

```
int iauTaiutc(double tai1, double tai2, double *utc1, double *utc2)
* *
     iauTaiutc
* *
    Time scale transformation: International Atomic Time, TAI, to Coordinated Universal Time, UTC.
* *
* *
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical.
* *
* *
    Given:
* *
       tail,tail double TAI as a 2-part Julian Date (Note 1)
* *
* *
    Returned:
* *
       utc1,utc2 double
                            UTC as a 2-part quasi Julian Date (Notes 1-3)
* *
* *
    Returned (function value):
* *
                   int
                             status: +1 = dubious year (Note 4)
* *
                                       0 = OK
* *
                                      -1 = unacceptable date
* *
* *
    Notes:
* *
* *
    1) tail+tai2 is Julian Date, apportioned in any convenient way
* *
       between the two arguments, for example where tail is the Julian
* *
       Day Number and tai2 is the fraction of a day. The returned utcl
* *
       and utc2 form an analogous pair, except that a special convention
* *
       is used, to deal with the problem of leap seconds - see the next
* *
       note.
* *
* *
    2) JD cannot unambiguously represent UTC during a leap second unless
* *
       special measures are taken. The convention in the present
* *
       function is that the JD day represents UTC days whether the
* *
       length is 86399, 86400 or 86401 SI seconds.
* *
* *
    3) The function iauD2dtf can be used to transform the UTC quasi-JD
       into calendar date and clock time, including UTC leap second
* *
       handling.
* *
    4) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
* *
       to be trusted. See iauDat for further details.
* *
* *
    Called:
* *
       iauJd2cal
                     JD to Gregorian calendar
* *
                     delta(AT) = TAI-UTC
       iauDat
* *
       iauCal2jd
                     Gregorian calendar to JD
* *

The returned \* \* tcb1,tcb2 follow suit. \* \* \* \* 2) The 2006 IAU General Assembly introduced a conventional linear transformation between TDB and TCB. This transformation \* \* \* \* compensates for the drift between TCB and terrestrial time TT, and keeps TDB approximately centered on TT. Because the relationship between TT and TCB depends on the adopted solar \* \* \* \* \* \* system ephemeris, the degree of alignment between TDB and TT over \* \* long intervals will vary according to which ephemeris is used. \* \* Former definitions of TDB attempted to avoid this problem by \* \* stipulating that TDB and TT should differ only by periodic \* \* effects. This is a good description of the nature of the \* \* relationship but eluded precise mathematical formulation. \* \* conventional linear relationship adopted in 2006 sidestepped \* \* these difficulties whilst delivering a TDB that in practice was consistent with values before that date. \* \* \* \* 3) TDB is essentially the same as Teph, the time argument for the \* \* JPL solar system ephemerides. \* \* \* \* Reference: \* \* \* \* IAU 2006 Resolution B3

```

* *
    iauTdbtt
* *
* *
* *
    Time scale transformation: Barycentric Dynamical Time, TDB, to
* *
    Terrestrial Time, TT.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical.
* *
* *
    Given:
* *
       tdb1,tdb2 double
                              TDB as a 2-part Julian Date
* *
                              TDB-TT in seconds
       dtr
                   double
* *
* *
    Returned:
* *
       tt1,tt2
                   double
                              TT as a 2-part Julian Date
* *
* *
    Returned (function value):
* *
                             status: 0 = OK
* *
* *
    Notes:
* *
* *
    1) tdb1+tdb2 is Julian Date, apportioned in any convenient way
* *
       between the two arguments, for example where tdb1 is the Julian
* *
       Day Number and tdb2 is the fraction of a day. The returned
* *
       tt1,tt2 follow suit.
* *
* *
    2) The argument dtr represents the quasi-periodic component of the
* *
       GR transformation between TT and TCB. It is dependent upon the
* *
       adopted solar-system ephemeris, and can be obtained by numerical
* *
       integration, by interrogating a precomputed time ephemeris or by
       evaluating a model such as that implemented in the SOFA function iauDtdb. The quantity is dominated by an annual term of 1.7 ms
* *
* *
* *
       amplitude.
* *
    3) TDB is essentially the same as Teph, the time argument for the
* *
       JPL solar system ephemerides.

* *
                            Delta UT1: UT1-UTC in seconds (Note 2)
       dut.1
                  double
* *
* *
    Returned:
* *
      utc1,utc2 double
                            UTC as a 2-part quasi Julian Date (Notes 3,4)
* *
* *
    Returned (function value):
* *
                            status: +1 = dubious year (Note 5)
                   int
* *
                                     0 = OK
* *
                                     -1 = unacceptable date
* *
* *
    Notes:
* *
* *
    1) ut11+ut12 is Julian Date, apportioned in any convenient way
* *
       between the two arguments, for example where utll is the Julian
* *
       Day Number and ut12 is the fraction of a day. The returned utc1
* *
       and utc2 form an analogous pair, except that a special convention
* *
       is used, to deal with the problem of leap seconds - see Note 3.
* *
* *
    2) Delta UT1 can be obtained from tabulations provided by the
* *
       International Earth Rotation and Reference Systems Service.
* *
       value changes abruptly by 1s at a leap second; however, close to
* *
       a leap second the algorithm used here is tolerant of the "wrong"
* *
       choice of value being made.
* *
    3) JD cannot unambiguously represent UTC during a leap second unless
       special measures are taken. The convention in the present
* *
       function is that the returned quasi JD day UTC1+UTC2 represents
* *
       UTC days whether the length is 86399, 86400 or 86401 SI seconds.
* *
* *
    4) The function iauD2dtf can be used to transform the UTC quasi-JD
* *
       into calendar date and clock time, including UTC leap second
* *
       handling.
* *
* *
    5) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
       to be trusted. See iauDat for further details.
* *
* *
* *
    Called:

```

```
int iauUtctai(double utc1, double utc2, double *tai1, double *tai2)
* *
     iauUtctai
* *
* *
    Time scale transformation: Coordinated Universal Time, UTC, to
* *
    International Atomic Time, TAI.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical.
* *
* *
    Given:
* *
       utcl,utc2 double UTC as a 2-part quasi Julian Date (Notes 1-4)
* *
* *
    Returned:
* *
        tai1,tai2 double
                              TAI as a 2-part Julian Date (Note 5)
* *
* *
    Returned (function value):
* *
                    int
                               status: +1 = dubious year (Note 3)
* *
                                         0 = OK
* *
                                        -1 = unacceptable date
* *
* *
    Notes:
* *
* *
    1) utcl+utc2 is quasi Julian Date (see Note 2), apportioned in any
* *
        convenient way between the two arguments, for example where utcl
* *
        is the Julian Day Number and utc2 is the fraction of a day.
* *
* *
    2) JD cannot unambiguously represent UTC during a leap second unless
       special measures are taken. The convention in the present function is that the JD day represents UTC days whether the
* *
* *
* *
        length is 86399, 86400 or 86401 SI seconds.
* *
    3) The warning status "dubious year" flags UTCs that predate the introduction of the time scale and that are too far in the future
* *
* *
* *
        to be trusted. See iauDat for further details.
* *
    4) The function iauDtf2d converts from calendar date and time of day
* *
        into 2-part Julian Date, and in the case of UTC implements the
* *
        leap-second-ambiguity convention described above.
* *
    5) The returned TAI1, TAI2 are such that their sum is the TAI Julian
* *
       Date.
* *

                                       0 = OK
* *
                                       -1 = unacceptable date
* *
* *
    Notes:
* *
* *
    1) utcl+utc2 is quasi Julian Date (see Note 2), apportioned in any
* *
       convenient way between the two arguments, for example where utcl
* *
       is the Julian Day Number and utc2 is the fraction of a day.
* *
* *
    2) JD cannot unambiguously represent UTC during a leap second unless
       special measures are taken. The convention in the present
* *
       function is that the JD day represents UTC days whether the
* *
       length is 86399, 86400 or 86401 SI seconds.
* *
* *
    3) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
* *
       to be trusted. See iauDat for further details.
* *
    4) The function iauDtf2d converts from calendar date and time of day into 2-part Julian Date, and in the case of UTC implements
* *
* *
       the leap-second-ambiguity convention described above.
* *
    5) Delta UT1 can be obtained from tabulations provided by the
* *
       International Earth Rotation and Reference Systems Service. It
       It is the caller's responsibility to supply a DUT argument containing the UT1-UTC value that matches the given UTC.
* *
* *
* *
* *
    6) The returned utl1,utl2 are such that their sum is the UTl Julian
* *
       Date.
* *
* *
    7) The warning status "dubious year" flags UTCs that predate the
* *
       introduction of the time scale and that are too far in the future
* *
       to be trusted. See iauDat for further details.
* *

```

```
void iauXy06(double date1, double date2, double *x, double *y)
* *
     iauxy06
* *
* *
* *
    X,Y coordinates of celestial intermediate pole from series based
* *
    on IAU 2006 precession and IAU 2000A nutation.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: canonical model.
* *
* *
    Given:
* *
       date1,date2 double
                                TT as a 2-part Julian Date (Note 1)
* *
* *
    Returned:
* *
                               CIP X,Y coordinates (Note 2)
                     double
       х,у
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
              date1
                              date2
* *
* *
           2450123.7
                                 0.0
                                            (JD method)
                            -1421.3
* *
                                            (J2000 method)
           2451545.0
* *
            2400000.5
                            50123.2
                                            (MJD method)
* *
           2450123.5
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
* *
       is acceptable. The J2000 method is best matched to the way
       the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
    2) The X,Y coordinates are those of the unit vector towards the
* *
       celestial intermediate pole. They represent the combined effects
       of frame bias, precession and nutation.
* *
* *
    3) The fundamental arguments used are as adopted in IERS Conventions
* *
       (2003) and are from Simon et al. (1994) and Souchay et al.
* *
       (1999).
* *
    4) This is an alternative to the angles-based method, via the SOFA
* *
       function iauFw2xy and as used in iauXys06a for example. The two
* *
       methods agree at the 1 microarcsecond level (at present), a
* *
       negligible amount compared with the intrinsic accuracy of the
* *
       models. However, it would be unwise to mix the two methods
* *
       (angles-based and series-based) in a single application.

       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
                               date2
               date1
* *
* *
            2450123.7
                                 0.0
                                            (JD method)
* *
                             -1421.3
            2451545.0
                                            (J2000 method)
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
            2450123.5
                                 0.2
                                            (date & time method)
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
       is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) The Celestial Intermediate Pole coordinates are the x,y
* *
       components of the unit vector in the Geocentric Celestial
* *
       Reference System.
* *
* *
    3) The CIO locator s (in radians) positions the Celestial
* *
       Intermediate Origin on the equator of the CIP.
* *
* *
    4) The present function is faster, but slightly less accurate (about
* *
       1 mas in X,Y), than the iauXys00a function.
* *
* *
    Called:
* *
       iauPnm00b
                     classical NPB matrix, IAU 2000B
* *
       iauBpn2xy
                     extract CIP X,Y coordinates from NPB matrix
* *
                     the CIO locator s, given X,Y, IAU 2000A
       iauS00
* *
* *
    Reference:
* *
* *
       McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003),
* *
       IERS Technical Note No. 32, BKG (2004)
* *
```

```
void iauXys06a(double date1, double date2,
                double *x, double *y, double *s)
* *
* *
    iauXys06a
* *
* *
* *
    For a given TT date, compute the X,Y coordinates of the Celestial
    Intermediate Pole and the CIO locator s, using the IAU 2006
* *
* *
    precession and IAU 2000A nutation models.
* *
* *
    This function is part of the International Astronomical Union's
* *
    SOFA (Standards Of Fundamental Astronomy) software collection.
* *
* *
    Status: support function.
* *
* *
    Given:
* *
       date1, date2 double TT as a 2-part Julian Date (Note 1)
* *
* *
    Returned:
* *
                     double Celestial Intermediate Pole (Note 2)
       х,у
* *
       S
                     double the CIO locator s (Note 2)
* *
* *
    Notes:
* *
* *
    1) The TT date date1+date2 is a Julian Date, apportioned in any
* *
       convenient way between the two arguments. For example,
* *
       JD(TT)=2450123.7 could be expressed in any of these ways,
* *
       among others:
* *
* *
                               date2
               date1
* *
* *
            2450123.7
                                 0.0
                                            (JD method)
* *
                             -1421.3
            2451545.0
                                             (J2000 method)
* *
            2400000.5
                             50123.2
                                            (MJD method)
* *
                                             (date & time method)
            2450123.5
                                 0.2
* *
* *
       The JD method is the most natural and convenient to use in
* *
       cases where the loss of several decimal digits of resolution
       is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the
* *
* *
       optimum resolution. The MJD method and the date & time methods
* *
       are both good compromises between resolution and convenience.
* *
* *
    2) The Celestial Intermediate Pole coordinates are the x,y components
* *
       of the unit vector in the Geocentric Celestial Reference System.
* *
* *
    3) The CIO locator s (in radians) positions the Celestial
* *
       Intermediate Origin on the equator of the CIP.
* *
* *
    4) Series-based solutions for generating X and Y are also available:
* *
       see Capitaine & Wallace (2006) and iauXy06.
* *
* *
    Called:
* *
       iauPnm06a
                     classical NPB matrix, IAU 2006/2000A
* *
                     extract CIP X,Y coordinates from NPB matrix
       iauBpn2xy
* *
       iauS06
                     the CIO locator s, given X,Y, IAU 2006

SOFA Software License

NOTICE TO USER:

BY USING THIS SOFTWARE YOU ACCEPT THE FOLLOWING SIX TERMS AND CONDITIONS WHICH APPLY TO ITS USE.

- 1. The Software is owned by the IAU SOFA Board ("SOFA").
- 2. Permission is granted to anyone to use the SOFA software for any purpose, including commercial applications, free of charge and without payment of royalties, subject to the conditions and restrictions listed below.
- 3. You (the user) may copy and distribute SOFA source code to others, and use and adapt its code and algorithms in your own software, on a world-wide, royalty-free basis. That portion of your distribution that does not consist of intact and unchanged copies of SOFA source code files is a "derived work" that must comply with the following requirements:
  - a) Your work shall be marked or carry a statement that it (i) uses routines and computations derived by you from software provided by SOFA under license to you; and (ii) does not itself constitute software provided by and/or endorsed by SOFA.
  - b) The source code of your derived work must contain descriptions of how the derived work is based upon, contains and/or differs from the original SOFA software.
  - c) The name(s) of all routine(s) in your derived work shall not include the prefix "iau" or "sofa" or trivial modifications thereof such as changes of case.
  - d) The origin of the SOFA components of your derived work must not be misrepresented; you must not claim that you wrote the original software, nor file a patent application for SOFA software or algorithms embedded in the SOFA software.
  - e) These requirements must be reproduced intact in any source distribution and shall apply to anyone to whom you have granted a further right to modify the source code of your derived work.

Note that, as originally distributed, the SOFA software is intended to be a definitive implementation of the IAU standards, and consequently third-party modifications are discouraged. All variations, no matter how minor, must be explicitly marked as such, as explained above.

4. You shall not cause the SOFA software to be brought into disrepute, either by misuse, or use for inappropriate tasks, or by inappropriate modification.

\*

- 5. The SOFA software is provided "as is" and SOFA makes no warranty as to its use or performance. SOFA does not and cannot warrant the performance or results which the user may obtain by using the SOFA software. SOFA makes no warranties, express or implied, as to non-infringement of third party rights, merchantability, or fitness for any particular purpose. In no event will SOFA be liable to the user for any consequential, incidental, or special damages, including any lost profits or lost savings, even if a SOFA representative has been advised of such damages, or for any claim by any third party.
  - 6. The provision of any version of the SOFA software under the terms and conditions specified herein does not imply that future versions will also be made available under the same terms and conditions.

In any published work or commercial product which uses the SOFA software directly, acknowledgement (see www.iausofa.org) is appreciated.

Correspondence concerning SOFA software should be addressed as follows:
